Preface

The *SMCC NFS Server Performance and Tuning Guide* is about the NFS™ distributed computing file system. It describes:

- NFS and network performance analysis and tuning
- NFS and network monitoring tools

This book is written with these assumptions about your server:

- It runs the SolarisTM 2.4, 2.5, 2.5.1, 2.6, or 7 operating environment.
- It is set up in a networked configuration.
- It is a SPARCserverTM system, SPARCcenterTM 2000(E), NetraTM NFS 150 Server, or a SunTM EnterpriseTM 3x00, 4x00, 5x00, or 6x00 system.

This book is for system administrators and network specialists who configure, analyze performance, or tune servers that provide the NFS service to network clients. It discusses NFS version 2 and version 3 tuning for the Solaris 2.4, 2.5, 2.5.1, 2.6, and 7 operating environments.

Typographic Conventions

TABLE P-1 Typographic Conventions

Typeface or Symbol	Meaning	Examples
AaBbCc123	The names of commands, files, and directories; on-screen computer output.	Edit your .login file. Use ls -a to list all files. % You have mail.
AaBbCc123	What you type, when contrasted with on-screen computer output.	% su Password:
AaBbCc123	Book titles, new words or terms, words to be emphasized. Command-line variable; replace with a real name or value.	Read Chapter 6 in the <i>User's Guide</i> . These are called <i>class</i> options. You <i>must</i> be root to do this. To delete a file, type rm <i>filename</i> .

Shell Prompts

TABLE P-2 Shell Prompts

NFS Overview

This chapter briefly discusses NFS characteristics, the tuning cycle, and third-party tools used to monitor NFS activity.

NFS Characteristics

The NFS environment provides transparent file access to remote files over a network. File systems of remote devices appear to be local. Clients access remote file systems by using either the mount command or the automounter.

The NFS protocol enables multiple client retries and easy crash recovery. The client provides all of the information for the server to perform the requested operation. The client retries the request until it is acknowledged by the server, or until it times out. The server acknowledges writes when the data is flushed to nonvolatile storage.

The multithreaded kernel does not require the maintenance of multiple nfsd or asynchronous-block I/O daemon(biod) processes; they are both implemented as operating system kernel threads. There are no biods on the client and one nfsd process exists on the server.

NFS traffic is characterized by its random patterns. NFS requests, which are usually of many types, are generated in bursts. The capacity of an NFS server must address the bursty nature of NFS file service demands. Demand varies widely but is relatively predictable during normal activity.

Most requests from applications (which may be local or remote), follow this pattern:

- 1. The user reads in the sections of the application binary then executes the code pages leading to a user dialog, which specifies a data set on which to operate.
- 2. The application reads the data set from the remote disk.

- 3. The user can then interact with the application, manipulating the in-memory representation of the data. This phase continues for most of the runtime of the application.
- 4. The modified data set is saved to disk.

More sections of the application binary may be paged in as the application continues to run.

NFS Version 2 and Version 3

The Solaris 2.5 through Solaris 7 operating environments are shipped with NFS Version 2 and NFS version 3. NFS version 3 is a new addition to the Solaris operating environments beginning with Solaris 2.5.

The NFS client negotiates with the server regarding whether to use NFS version 2 or NFS version 3. If the server supports NFS version 3, then version 3 becomes the default to use. You can override the default NFS version used with the vers= mount option.

You tune NFS version 2 and NFS version 3 similarly.

NFS Version 3 Features and Operations

NFS version 3 contains several features to improve performance, reduce server load, and reduce network traffic. Since NFS version 3 is faster for I/O writes, and uses fewer operations over the network, you will have more efficient use of the network. Note that higher throughput may make the network busier.

NFS version 3 maintains the stateless server design and simple crash recovery of version 2 along with its approach to build a distributed file service from cooperating protocols.

TABLE 1-1 describes the NFS operations and their functions for versions 2 and 3. TABLE 1-2 lists the NFS operations new to Version 3.

NFS Operations in Version 2 and Version 3 TABLE 1-1

Operation	Function in Version 2	Change in Version 3
create	Creates a file system node; may be a file or a symbolic link	No change
statfs	Gets dynamic file system information	Replaced by fsstat
getattr	Gets file or directory attributes such as file type, size, permissions, and access times	No change
link	Creates a hard link in the remote file system	No change
lookup	Searches directory for file and return file handle	No change
mkdir	Creates a directory	No change
null	Does nothing; used for testing and timing of server response	No change
read	Reads an 8-Kbyte block of data (32-KByte blocks). This can be raised beyond 64 KBytes for TCP.	Block of data up to 4 Gbytes
readdir	Reads a directory entry	No change
readlink	Follows a symbolic link on the server	No change
rename	Changes the directory name entry	No change
remove	Removes a file system node	No change
rmdir	Removes a directory	No change
root	Retrieves the root of the remote file system (not presently used)	Removed
setattr	Changes file or directory attributes	No change
symlink	Makes a symbolic link in a remote file system	No change
wrcache	Writes an 8 Kbyte block of data to the remote cache (not presently used)	Removed
write	Writes an 8 Kbyte block of data (32-KByte blocks). This can be raised beyond 64 KBytes for TCP.	Block of data up to 4 Gbytes

TABLE 1-2 New NFS Operations in Version 3

Operation in Version 3	Function
access	Check access permission
mknod	Create a special device
readdir	Read from directory

TABLE 1-2 New NFS Operations in Version 3

Operation in Version 3	Function
readdirplus	Extended read from directory
fsinfo	Get static file system information
pathconf	Retrieve POSIX information
commit	Commit cached data on a server to stable storage

Changes in Version 3 from Version 2

The root and writecache operations have been removed. A mknod operation has been defined to allow the creation of special files, thus eliminating the overloading of create. Caching on the client is not defined nor dictated by Version 3. Additional information and hints have been added to Version 3 to allow clients that implement caching to manage their caches more effectively.

Operations that affect the attributes of a file or directory may now return the new attributes after the operation has completed to optimize out a subsequent getattr used in validating attribute caches. Also, operations that modify the directory in which the target object resides return the old and new attributes of the directory to allow clients to implement more intelligent cache invalidation procedures.

The access operation provides access permission checking on the server. The fsstat operation returns static information about a file system and server. The readdirplus operation returns file handles and attributes in additional to directory entries. The pathconf operation returns POSIX pathconf information about a file.

64-Bit File Size

Version 3 of the NFS protocol enables access to files whose length fits in 64 bits. With version 2, the length had to fit in 32 bits (4 Gbytes).

Access to large files (64-bit) is possible only if the client, server, and the operating system support large files. If the client implementation is limited to 32-bit files, then the client can't access files larger than 32 bits (even if the server supports them). Conversely, if the client supports 64-bit files but the server only supports 32-bit files, the client is limited to 32-bit files. The Solaris 7 operating environment is the first Solaris release that takes advantage of this protocol feature. Operating environments prior to Solaris 7 did *not* have 64-bit file support.

The limit for the UNIX File System in the Solaris 2.6 and 7 operating environments is 1 Terrabyte (40 bits).

Asynchronous Writes

NFS version 3 can use asynchronous writes, which is optional. The NFS version 3 client sends asynchronous write requests to the server, which acknowledges receiving the data. However, the server is not required to write the data to stable storage before replying. The server may schedule the write, or wait to gather multiple write requests together.

The client maintains a copy of the data in case the server is unable to complete the writes. When the client wants to free its copy, it notifies the server with a COMMIT operation. The server responds positively only after it ensures that the data is written to stable storage. Otherwise, it responds with an error and the client resends the data synchronously.

Asynchronous writes enable the server to determine the best policy to synchronize the data. The data is most likely synchronized by the time the COMMIT arrives. Compared with NFS version 2, this scheme enables better buffering and more parallelism.

With NFS version 2, the server does not respond to a write request until the data is placed in stable storage. However, it may use techniques such as write gathering to issue multiple concurrent requests before responding to any of the requests.

Read Directory With Attributes

NFS version 3 contains an operation called READDIRPLUS. Most READDIRS are now issued as READDIRPLUS calls; for example, an ls or an ls -l triggers READDIRPLUS calls. When the ls -l commands run over version 3, the file handles and attributes are returned with the list of names in the directory. In version 2, the names are returned first, then additional calls to the server are required to obtain the file handles and attributes.

The advantage of the READDIRPLUS operation in version 3 is that an ls and an ls -1 are now comparable in speed because separate GETATTR requests are not required for each file.

Weak Cache Consistency

Many NFS version 2 clients cache file and directory data to improve performance. At times, the version 2 method fails when multiple clients are sharing and caching the same data.

Weak cache consistency enables the client to detect data changes between its last access and the current request. This is done when the server sends back the previous attributes with the response. The client can then compare the previous attributes with what it thought the previous attributes were and detect the changes.

Tuning Cycle

FIGURE 1-1 shows a flowchart of the tuning cycle:

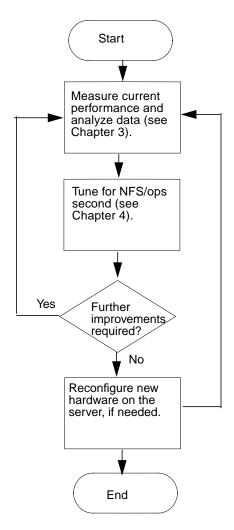

FIGURE 1-1 Overview of the Tuning Cycle

Third Party Tools

Some of the third party tools you can use for NFS and networks include:

- NetMetrix (Hewlett-Packard)
- SharpShooter (Network General Corporation, formerly AIM Technology)

SharpShooter (version 3) understands the NFS version 3 protocol.

Hardware Overview

This chapter provides an overview of the following NFS servers and expansion units:

- Sun Enterprise 1 system
- Sun Enterprise 2 system
- SPARCserver 20 system
- Sun Enterprise 150 system
- Sun Enterprise 250 system
- Sun Enterprise 450 system
- Sun Enterprise 4000, 5000, and 6000 systems
- Sun Enterprise 3500, 4500, 5500, and 6500 systems
- SPARCserver 1000 or SPARCserver 1000E system
- SPARCcenter 2000 or SPARCserver 2000E system
- Netra NFS Server system
- SPARCstorage Array subsystem
- Sun StorEdge[™] A1000 RAID Disk Array
- Sun StorEdge A3000 subsystem
- Sun StorEdge A5000 subsystem
- Sun StorEdge A7000 Intelligent Storage Server
- SPARCstorage MultiPack enclosure
- SPARCstorage UniPack enclosure

NFS File Servers

This section provides a hardware overview of Sun NFS servers. TABLE 2-1 illustrates the conditions under which a particular NFS file server will meet your needs. This table is arranged by first presenting the Netra NFS Server, a dedicated NFS server. Next, the table presents high capacity enterprise servers followed by workgroup

servers. Workgroup servers are dedicated to a group, department, or small organization that shares common resources or tasks. Workgroup servers usually provide a specific function such as an NFS file server.

 TABLE 2-1
 NFS Server Comparison Table

Server	Maximum Specifications	Positioning	Key Advantages
Netra NFS Server	—100 NFS clients —24 Gbytes of internal disk storage (48 Gbytes with 4 Gbyte disk drives) —2 subnets with Fast Ethernet (100 BaseT), Token Ring, FDDI —9 subnets with 10BaseT Ethernet	Dedicated NFS server supporting both workgroup and department needs	Industry leading NFS price/ performance with RAID 5; Fast response times; easy to administer with HTML user interface; highly reliable with internal UPS and RAID 5; includes PC-NFS server software; exclusively supports NFS applications; RAID 5 and single file system is preconfigured
Sun Enterprise 6000	 —At least 600 NFS clients —189 Gbytes of disk storage (system enclosure only) —More than 20 subnets per system —Ethernet, optional FDDI, SunATM, and Token Ring 	Most scalable and expandable Sun server	Handles a minimum of 14,000 ops/second, which is equivalent to 140,000 PC clients; handles arbitrary NFS client loads
Sun Enterprise 5000	 —At least 400 NFS clients —233 Gbytes of disk storage (system enclosure only) —More than 20 subnets per system —Ethernet, optional FDDI, SunATM, and Token Ring 	Data center server system	Delivers high performance and high availability for enterprise wide applications supporting thousands of users; able to handle arbitrary NFS client loads
Sun Enterprise 4000	 —At least 400 NFS clients —168 Gbytes of disk storage (system enclosure only) —More than 20 subnets per system —Ethernet, optional FDDI, SunATM, and Token Ring 	Compact yet highly expandable system	Delivers high performance scalability for department applications in a distributed network computing environment; handles arbitrary NFS client loads

 TABLE 2-1
 NFS Server Comparison Table (Continued)

Server	Maximum Specifications	Positioning	Key Advantages
Sun Enterprise 3000	 —At least 300 NFS clients —42 Gbytes of disk storage (system enclosure only) —More than 20 subnets per system — Ethernet, optional FDDI, SunATM, and Token Ring 	Affordable departmental server	Applications support up to hundreds of users in an office environments; handles arbitrary NFS client loads
Sun Enterprise 6500	 —382 Gbytes internal storage (system cabinet only) —Greater than 10 Terabytes of total disk storage —30 CPUs and 30 Gbytes of memory 	High end datacenter server	Handles arbitrary NFS client loads; Dynamic Reconfiguration, Alternate Pathing, and CPU power control
Sun Enterprise 5500	 —509 Gbytes of internal storage (system cabinet only) —Greater than 6 Terabytes of maximum disk storage —14 CPUs and 14 Gbytes of memory 	Entry level datacenter server	Handles arbitrary NFS client loads; Dynamic Reconfiguration, Alternate Pathing, and CPU power control
Sun Enterprise 4500	 —33.6 Gbytes of internal storage (system only) —Greater than 4 Terabytes of total disk storage —14 CPUs and 14 Gbytes of memory 	High end departmental server	Handles arbitrary NFS client loads; Dynamic Reconfiguration, Alternate Pathing, and CPU power control
Sun Enterprise 3500	 —72.8 Gbytes of internal storage (system only) —Greater than 2 Terabytes of total disk storage —8 CPUs and up to 8 Gbytes of memory 	Entry level departmental server	Handles arbitrary NFS client loads; Dynamic Reconfiguration, Alternate Pathing, and CPU power control
SPARCcenter 2000 or 2000E	 —500 NFS clients —36 subnets —731 Gbytes of storage —Ethernet, FDDI, SunATM, and Token Ring 	Highest capacity; multipurpose enterprise server (the total solution for an entire company)	Centralized administration maximum headroom for growth; multiprocessor, I/ O, and network performance scalability

 TABLE 2-1
 NFS Server Comparison Table (Continued)

Server	Maximum Specifications	Positioning	Key Advantages
SPARCserver 1000 or 1000E	—300 NFS clients —12 subnets —395 Gbytes of storage —Ethernet, FDDI, SunATM, and Token Ring	High capacity multipurpose workgroup server	Excellent capacity performance; multipurpose server (NFS, compute, database), affordable, scalable, integrated packaging
Sun Enterprise 450	—Used in environments that require large amounts of disk storage with fast or multiple I/O channels to clients or to the network	Mid-range server	Supports RAID 1 (disk mirroring), RAID 3 (striping data and parity across drive groups), and RAID 5 (hot spares for FC-AL disks)
Sun Enterprise 250 Server	—Up to 54 Gbytes of disk storage, dual CPU processor, and fast PCI I/ O channels	Mid-range server	Supports RAID 0 (disk striping), RAID 1 (disk mirroring), and RAID 5 (hot spares); automated hardware failure notification; hot sparing support
Sun Enterprise 150 Server	—Internal disk array with up to twelve hot- plugable disks providing 48 Gbytes of disk capacity (based on 4 Gbyte disks)	High end workgroup server	Supports RAID 0 (disk striping) RAID 1 (disk mirroring) and RAID 5 (hot spares); high level of I/O throughput and capacity; significant expansion capabilities; advanced I/O and networking

 TABLE 2-1
 NFS Server Comparison Table (Continued)

Server	Maximum Specifications	Positioning	Key Advantages
Sun Enterprise 2	—At least 350-400 NFS clients —67 Gbytes of disk storage (4 Gbytes in the system and 63 Gbytes in the SPARCstorage Array) —4 subnets —Ethernet, optional FDDI and SunATM	High performance multiprocessing server for mid to large size workgroups	High throughput for multiprocessing; high application performance; efficient design and process handling
Sun Enterprise 1	 —200-220 NFS clients —147 Gbytes of storage — 4 subnets —Ethernet, optional FDDI and SunATM 	High capacity; medium to large workgroup server (50 to 100 users)	Excellent performing uniprocessor workgroup server that simplifies administration and lowers costs
SPARCserver 20	 —125 NFS clients —138 Gbytes of storage —4 subnets —Ethernet, FDDI, SunATM, and Token Ring 	Low cost; multipurpose workgroup server PC LAN server	Low cost, powerful, flexible, and easily redeployed

Dedicated NFS Servers

This section presents an overview of the Netra NFS Server system.

Netra NFS Server System

The Netra NFS Server system provides an easily managed, highly reliable, highly tuned dedicated NFS server. It is built exclusively to support NFS applications; Solaris software environment applications are not supported. This Netra NFS server provides superior NFS operations performance over general purpose servers.

The key benefits of this Netra NFS server include:

- Easy installation (preconfigured system)
- Easy HTML management interface with the LCD system status and input panel
- Factory preconfigured RAID-5 disks
- Dedicated, simplified operation set
- Tuned for NFS performance
- System reliability (UPS for graceful shutdown on power failure)
- Uninterruptable power supply

This server meets the demands of high speed network environments. Because this server delivers high performance for NFS operations, it is most often installed in departments and workgroups where data access requirements are high and other servers are available for running applications and system management software (see FIGURE 2-1).

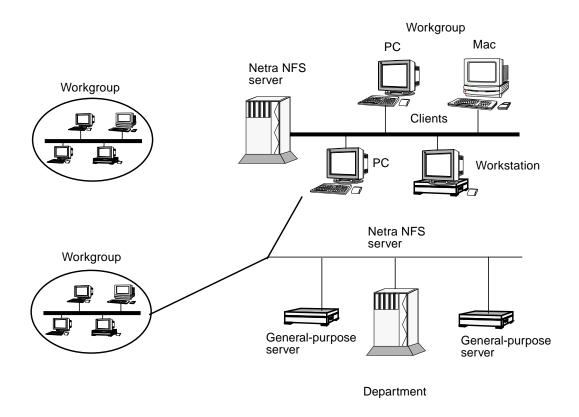

FIGURE 2-1 Environments Supported by the Netra NFS Server

As FIGURE 2-1 shows, the Netra NFS Server system supports both workgroup and department needs.

Netra NFSServer Software Support

The easy to use customized Netra NFS SmartServeTM software, which is focused exclusively on NFS applications, is tuned for NFS performance and is easy to administer. The software has the following features:

■ Modified Solaris operating environment (dedicated and optimized for NFS)

- SNMP agent
- Single file system and RAID 5 preconfigured
- Backup software for online backups
- Support for NFS Version 2 and NFS Version 3
- Disk management support (RAID level 5 for storage management)
- Failure management and recovery
- System performance tuning (stable memory and NFS Smart Cache)
- PCNFSD (to use with NFS on PCs)

Netra NFS Server Hardware Overview

This server is based on the Ultra 1 processor board, which is designed to deliver balanced system performance. With twelve slots of data disks, the data disk capacity of this server is 24 Gbytes (48 Gbytes with 4 Gbyte disk drives). The disk drives are hot plugable. A 10BaseT Ethernet controller is built onboard.

One of the three SBus slots are used for ISP controllers. The second SBus slot contains a 100BaseT network card. The third SBus slot is available for additional network interfaces.

This system comes in two options: tower and rack-ready. Four rack-ready systems can be installed in standard Sun racks. The system also has a standard 3.5-inch diskette drive and a 644 Mbyte capacity CD-ROM drive. The eight SIMM slots can store up to 512 Mbytes of RAM.

Enterprise Servers

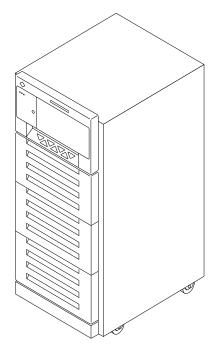

Sun has a range of enterprise servers. This section discusses the following enterprise servers:

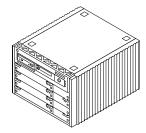

- Sun Enterprise 4x00, 5x00, and 6x00 servers
- SPARCcenter 2000/2000E servers
- SPARCserver 1000/1000E servers

Sun Enterprise 4000, 5000, and 6000 Systems

The Sun Enterprise 6000 server system, the Sun Enterprise 5000 server system and the Sun Enterprise 4000 server system are available in two enclosures (see FIGURE 2-2):

- Enterprise 6000 or 5000 is a 56-inch cabinet containing either a 16-slot or 8-slot card cage.
- Enterprise 4000 is a stand-alone enclosure containing an 8-slot card cage.

Sun Enterprise 6000/5000 are 16-slot or 8-slot cabinet servers

Sun Enterprise 4000 is an 8-slot stand-alone server

FIGURE 2-2 Sun Enterprise 6000 and 5000 Server Cabinet System and Sun Enterprise 4000 Stand-alone System

The same CPU/memory board, I/O boards, disk board, processor modules, memory SIMMs, power modules, and cooling modules are used in all enclosures.

The minimum configuration for the Sun Enterprise 4000, 5000, and 6000 is:

- 16-slot or 8-slot card cage
- Modular power supply
- Fan tray (cabinet servers) or fan box (standalone server)
- Clock board
- CPU/memory board
- I/O board
- Peripheral power supply
- AC distribution unit
- SCSI receptacle for removable media, including CD-ROM

Sun Enterprise systems have extensive error detection mechanisms, and an Automatic System Reconfiguration (ASR) feature that enables the system to be rebooted with failed components (such as CPUs, memory, or I/O) disabled. When an error is detected, the system is reconfigured so that the board containing the failed components is placed in low power mode and is no longer accessible.

The hot-plugable feature inserts a new board into a powered up system, despite being "live," or being supplied with electrical power. Once a working board is added to a powered on system with the hot-plugable feature, the Solaris 2.5.1 or 2.6 software environments will not use the new board until the system is rebooted. The systems also support hot-plugable disk drives and redundant, hot-plugable power and cooling units.

High speed networking is supported by integrated 10 or 100 Mb Ethernet and optional ATM interface.

The systems support remote control administration, which enables remote rebooting and power cycling.

The system monitor for these servers is SolsticeTM SyMONTM, a system performance tool that you can use to:

- Monitor the performance of a large server with multiple processors, I/O, and disks.
- Optimize the configuration and throughput of the server.
- Identify hardware and software failures quickly. Failures range from major failures (CPU crash), to minor failures (slow cooling fan). Solstice SyMON identifies the component or software and its location.
- Monitor hardware performance to detect incipient hardware failure (soft read errors on a disk).

Sun Enterprise 3500, 4500, 5500, and 6500 Systems

The 3500-6500 mid range server line uses the 336 MHz UltraSPARC[™] processor and the 84MHz to 100 MHz interconnect called the Sun Gigaplane[™] system bus. This server family includes hot-pluggable disk drives, processors, power supplies and cooling. Dynamic Reconfiguration and Alternate Pathing software, which lets you add, remove, or replace system resources while maintaining application availability, is a new feature of these servers. The server family also has CPU power control, a new feature.

The Sun™ Enterprise™3500 server, designed to be an entry-level departmental server, is contained in a tower/deskside enclosure. It has five system slots that can be used for either CPU/memory boards or I/O boards and contains up to eight CPUs. It has up to 8 Gbytes of memory, 72.8 GBytes of internal disk storage, and can

provide greater than 2 Terabytes of maximum total disk storage. The system also includes one CD-ROM drive and an optional tape drive. It includes disk bays for eight dual-ported FC-AL disk drives.

The Sun Enterprise 4500 server is housed in a tabletop enclosure and has eight system slots providing capacity for up to 14 CPUs. It is designed to be a high end departmental server and has up to 14 Gbytes of memory. The server provides 33.6 Gbytes of interal storage and can provide up to 4 Terabytes of maximum total disk storage. The server also contains one tape drive.

The Sun Enterprise 5500 server, designed to be an entry-level datacenter server, also has eight system slots providing up to 14 CPUs but the enclosure is a 68-inch cabinet. It contains up to 14 Gbytes of memory. It provides up to 509 Gbytes of internal storage and has the capability to provide greater than 6 Terabytes of maximum total disk storage. The server also contains a tape library.

The Sun Enterprise 6500 server, a high-end datacenter server, also is housed in a 68-inch cabinet. It has 16 system slots and can contain up to 30 CPUs and 30 Gbytes of memory. The server provides 382 Gbytes of internal storage and can provide greater than 10 Terabytes of maximum total disk storage. The server also contains a tape library. The system rack provides support for multiple internal disk subsystems and tape options.

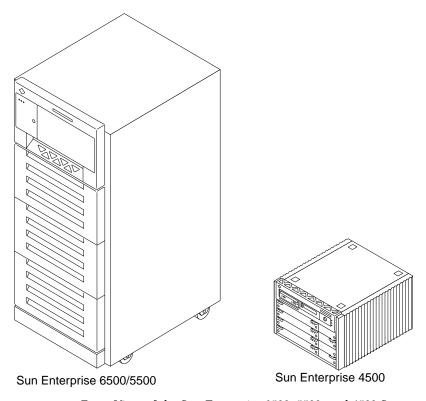

FIGURE 2-3 Front View of the Sun Enterprise 6500, 5500, and 4500 Servers

SPARCcenter 2000 and SPARCcenter 2000E Systems

The SPARCcenter 2000 and the SPARCcenter 2000E systems, which were introduced in 1992, provide the computing solution for a company. As such, the SPARCcenter 2000 system and the SPARCcenter 2000E system are multifunctional network NFS file servers. They support less than 500 NFS clients and have the flexibility required for dedicated or multifunctional application environments.

The SPARCcenter 2000 system and the SPARCcenter 2000E system provide scalability and extensive expansion in these areas:

- CPU processor power
- Memory capability
- I/O connectivity

They meet the following requirements:

- High capacity I/O requirements of corporate data centers
- Computationally intensive demands of other organizations

The heart of the SPARCcenter 2000 system or the SPARCcenter 2000E system is a high-speed packet-switched bus complex that provides very high data transfer bandwidth. The backplane supports two distinct XDBuses operating in parallel.

The SPARCcenter 2000 system or the SPARCcenter 2000E system use up to twenty SuperSPARCTM modules in a shared-memory symmetric multiprocessing configuration, meeting most performance needs. You can expand or upgrade the processing capability by adding SuperSPARC modules.

Main memory is configured in multiple logical units that are installed in the bus complex.

The I/O is expandable. For example, you can configure up to 40 SBus slots on 10 independent buses. The large I/O capacity and configurability makes the SPARCcenter 2000 system or the SPARCcenter 2000E system suitable for very large applications.

The system monitor for this server is Solstice SyMON.

SPARCserver 1000 and the SPARCserver 1000E System Features

The SPARCserver 1000 and the SPARCserver 1000E systems have the following features:

- Up to four system boards can be installed
- Up to eight SuperSPARC processors (two per system board) can be installed
- Up to 2 Gbytes of main memory (using 32 Mbyte SIMMs) can be installed
- Up to 16.8 Gbytes of internal storage
- 50 MHz system clock speed in the SPARCserver 1000E system (40 MHz in the SPARCserver 1000 system)
- 25 MHz SBus speed in the SPARCserver 1000E system (20 MHz in the SPARCserver 1000 system)
- When connected to 12 SPARCstorage Array subsystems, the SPARCserver 1000 or 1000E systems provide up to 756 Gbytes of external storage
- Up to 12 SBus slots
- Onboard SCSI-2 port and twisted pair Ethernet on each system board
- Internal 5 Gbyte 4mm tape drive (or 10 Gbyte 8mm tape drive)
- Internal CD-ROM drive
- NVRAM-NVSIMM Prestoserve NFS accelerator (optional)

Workgroup Servers

This section presents an overview of the following workgroup servers:

- Sun Enterprise 150 server system
- Sun Enterprise 250 serversystem

- Sun Enterprise 450 serversystem
- Sun Enterprise 2 server system
- Sun Enterprise 1 server system
- SPARCserver 20 server system

The highest capacity workgroup servers are presented first.

Sun Enterprise 150 Server System

The Sun Enterprise 150 server system is a tower workgroup server based on the 167 MHz UltraSPARC™ microprocessor. It has the following features:

- Autosensing 10/100 Mbps Fast Ethernet
- 10 Mbps Ethernet
- 20 Mbyte/second Fast/Wide SCSI-2 peripheral interface
- **■** ECC-protected memory
- Internal disk array with up to twelve hot-plugable disks supporting RAID 0 (disk striping), RAID 1 (disk mirroring), and RAID 5 (hot spares) providing 48 Gbytes of disk capacity (based on 4 Gbyte disk drives)
- 1.44 Mbyte diskette drive
- 644 Mbyte CD-ROM drive

The Sun Enterprise 150 server system is ideal for an NFS server because it is a highend workgroup server with high I/O performance and fast system throughput. FIGURE 2-4 shows a front view of the server.

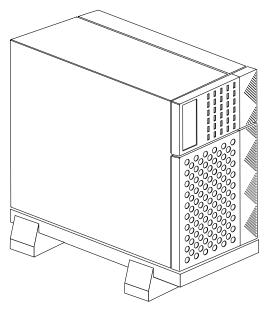

FIGURE 2-4 Sun Enterprise 150 Front View

For additional disk storage, you can attach either the Sun StorEdge UniPack or the Sun StorEdge MultiPack to the server. If you need greater amounts of disk storage, use the SPARCstorage Array to the server. For a backup device, use the SPARCstorage Library, which olds ten cartridges in a removable magazine for an average total capacity of 140 Mbytes.

Sun Enterprise 250 System

The Sun Enterprise 250 system server is a mid-range server with up to 54 Gbytes of disk storage, dual CPU processors, and fast PCI I/O channels.

Software features are:

- RAID 0 (disk striping), RAID 1 (disk mirroring), and RAID 5 (hot spares)
- System performance and configuration monitors
- Automated hardware failure notification
- Error and panic logging
- Temperature sensing and fan control
- Backup power supply failure detection
- Hot sparing support
- Automatic fault detection, response, and recovery
- Logging file systems

 Secure remote system monitoring feature for geographically distributed or physically inaccessible systems

Hardware features are:

- Four PCI slots supporting up to four full size PCI cards (three regular PCI slots and one enhanced PCI slot)
- Up to sixteen SIMM slots, which support 16, 32, 64, or 128 Mbyte SIMMs totaling up to 2 Gbytes of memory capacity
- 10/100 Mbit Ethernet
- 20 Mbyte/second Fast Wide SCSI
- Up to two CPU modules (UltraSPARC-II)
- Up to six 1.6-inch high or 1-inch high UltraSCSI disks
- 1.44 Mbyte diskette drive
- 644 Mbyte CD-ROM drive
- Two 5 1/4-inch x 1.6-inch removable media bays
- Two high speed synchronous/asynchronous serial ports
- Up to two redundant hot swapable power supplies
- Module to provide remote system monitoring capability
- Supports rack mounting allowing the system to integrate easily into a computer room environment

FIGURE 2-5 shows a front view of the Sun Enterprise 250 system.

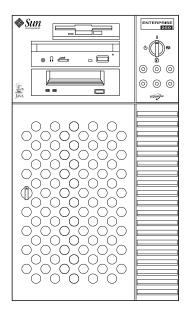

FIGURE 2-5 Sun Enterprise 250 Front View

Sun Enterprise 450 System

The Sun Enterprise 450 system server, based on the UltraSPARC-II™ processor, is designed for mid-range server markets that require large amounts of local disk storage with fast or multiple I/O channels to clients or to the network.

Software features are:

- Support for RAID 1 (disk mirroring), RAID 3 (striping data and parity across drive groups) and RAID 5 (hot spares for FC-AL disk drives)
- System performance and configuration monitors
- Automated hardware failure notification
- Error and panic logging
- Temperature sensing and fan control
- Backup power supply failure detection
- Hot sparing support
- Automatic fault detection, response, and recovery
- Logging file systems

Hardware features are:

- 10 PCI slots supporting up to 10 full size PCI cards (seven regular PCI slots and three enhanced PCI slots)
- Up to sixteen SIMM slots, which support 32, 64, 128 or 256 Mbyte SIMMs totalling up to 4 Gbytes of memory capacity
- 10/100 Mbit Ethernet
- 20 Mbyte/second Fast Wide SCSI
- Up to four CPU modules (UltraSPARC-II)
- Up to twenty hot swappable FC-AL disks and up to two 1.6-inch high SCSI disks that provide up to 84 Gbytes internal storage
- Up to 6 Terabytes of external disk storage
- 1.44 Mbyte diskette drive
- 644 Mbvte CD-ROM drive
- Two 5 1/4-inch bays for optional tape backup
- Two high speed synchronous/asynchronous serial ports
- Up to three redundant hot swapable power supplies, which can be added one at a time to improve reliability and provide growth as needed
- Supports rack mounting allowing the system to integrate easily into a computer room environment

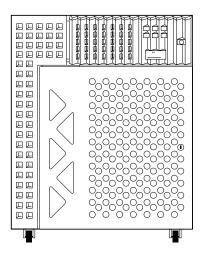

FIGURE 2-6 Front View of the Sun Enterprise 450 Server

You can attach up to two external tape devices or a single size or twelve drive Sun StorEdge MuliPack to the SCSI port. You can attach additional tape or disk devices by installing PCI host adapter cards. If you require large amounts of disk storage, you can also attach the Sun StorEdge A3000 subsystem to the system that provides a reduntant array of inexpensive disks (RAID).

Sun Enterprise 1 and 2 Systems

The Sun Enterprise 1 system is the first member of a new class of workstations based on the UltraSPARC-I processor and is designed to deliver balanced system performance.

The Sun Enterprise 1 system can be used as a high capacity NFS server for medium to large workgroups (50 to 100 users). It is designed for reliability, availability, and serviceability. It enables easy access to replace disk drives, SIMMs, and graphics cards.

The Sun Enterprise 2 system is a multiprocessor system based on the UltraSPARC-I processor. It is standard with Fast/Wide SCSI and Fast Ethernet, which enables the data throughput capability of this system to include the disk I/O and the network traffic. The system also has a 64-bit SBus running at 25 MHz giving maximum SBus throughput.

The Sun Enterprise 2 system can be used as an NFS server for mid- to large-sized workgroups.

The Ultra SPARC CPU is matched by a very high performance crossbar-switched interconnect that can move data at peak rates of 1.3 Gbytes/second. This interconnect, the Ultra Port Architecture (UPA), is the key to providing the greatly enhanced memory bandwidth. Both the Sun Enterprise 1 and 2 systems have a 64-bit SBus running at 25 MHz giving maximum SBus throughput.

The architecture was designed to be fully compatible with previous generations of workstations so that all Solaris operating environment applications can run unchanged.

FIGURE 2-7 shows a front view of the Sun Enterprise 1 system.

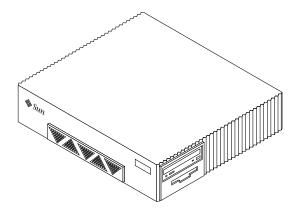

FIGURE 2-7 Sun Enterprise 1 Front View

SPARCserver 20 System

The SPARCserver 20 system, introduced in 1994, is designed to be a workgroup NFS file server or a database server in an office environment. It is based on the same MBus and SBus technologies as the SPARCserver 10 system. Performance is increased over the SPARCserver 10 by using faster MBus and SBus technology, and faster SPARC modules. The SPARCserver 20 system has increased computing and network performance.

The SPARCserver 20 system is available in three uniprocessor configurations and three multiprocessor configurations.

The uniprocessor configurations are:

- Model 50—50 MHz SuperSPARC processor
- Model 51—50 MHz SuperSPARC processor and 1 Mbyte SuperCache‰
- Model 61—60 MHz SuperSPARC processor and 1 Mbyte SuperCache
- Model 71—75 MHz SuperSPARC processor and 1 Mbyte SuperCache
- Model 151—one 150 MHz HyperSPARC processor and 0.5 Mbyte external cache

The multiprocessor configurations are:

- Model 502MP—two 50 MHz SuperSPARC processors
- Model 514MP—four 50 MHz SuperSPARC processors and 1 Mbyte SuperCache
- Model 612MP—two 60 MHz SuperSPARC processors and 1 Mbyte SuperCache
- Model 712—two 75 MHz SuperSPARC processors and 1 Mbyte SuperCache
- Model 152MP—two 150 MHz HyperSPARC processors and 0.5 Mbyte of external cache

FIGURE 2-8 shows the front view of the SPARCserver 20 system.

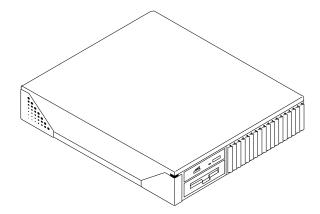

FIGURE 2-8 SPARCserver 20 System Front View

SPARCserver 20 System Features

The SPARCserver 20 system features include:

- More than 2 Gbytes of internal hard disk storage (two 1.05 Gbyte disk drives)
- Up to 126 Gbytes of disk storage in the SPARCstorage Array (Model 101) subsystems when directly connected to four SPARCstorage Array subsystems
- 1.44 Mbyte diskette drive (optional)
- 644 Mbyte CD-ROM drive (optional)
- Two serial ports, one parallel port
- Twisted-pair Ethernet
- Up to 512 Mbytes of memory (60 ns SIMMs)
- AUI Ethernet (optional) (can have up to 9 Ethernet networks)
- SBus or NVRAM-NVSIMM Prestoserve NFS accelerator (optional)

Disk Expansion Units

This section describes an overview of the following disk expansion units:

- SPARCstorage ArrayTM subsystem
- Sun StorEdge A1000 RAID system
- Sun StorEdge A3000 subsystem
- Sun StorEdge A5000 subsystem
- Sun StorEdge A7000 Intelligent Storage Server
- Sun StorEdge MultiPackTM
- Sun StorEdge UniPackTM

SPARCstorage Array Subsystem

To expand your disk storage, consider the SPARCstorage Array subsystem. This disk array is a high-performance and high-capacity companion unit for the Sun Enterprise 4000, 5000, or 6000 systems, SPARCcenter 2000 or 2000E, SPARCserver 1000 or 1000E, Sun Enterprise 150 system, Sun Enterprise 2 system, and the SPARCserver 20 system.

The Model 101 uses 1.05 Gbyte single connector 3.5-inch disk drives. Each disk array contains three drive trays. Each drive tray supports up to ten 3.5-inch single-connector SCSI disk drives. All disk drive SCSI addresses are hardwired. The position of the disk drive in the drive tray automatically sets the SCSI addresses. Each disk array uses six internal fast, wide SCSI buses. Each drive tray contains two SCSI buses that support five disk drives for each SCSI buse.

FIGURE 2-9 shows a front view of the SPARCstorage Array subsystem.

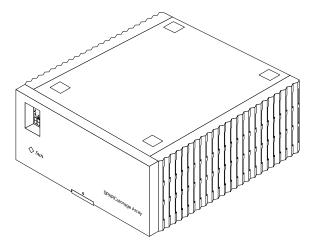

FIGURE 2-9 Front View of the SPARCstorage Array Subsystem

FIGURE 2-10 shows how you can connect the SPARCstorage Array subsystem to your NFS server.

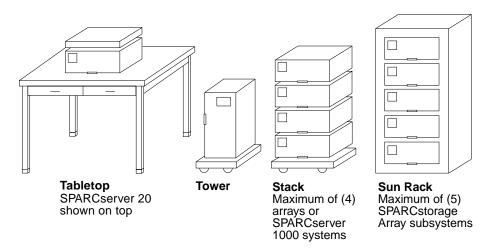

FIGURE 2-10 SPARCstorage Array Subsystem Installation Options

The SPARCstorage Array subsystem uses RAID (Redundant Array of Inexpensive Disks) technology. RAID 0 stripes data without parity, RAID 1 does disk mirroring, RAID 0+1 does mirroring optimized stripes, and RAID 5 does striping data with parity.

Within the disk array, independent disks plus RAID levels 5, 1, 0, 0+1 are available at the same time so you can easily match data layouts to meet the specific requirements for capacity, performance, high availability, and cost.

If any disk in a RAID-5, 1, or 0+1 group fails, an optional hot spare (if configured) is automatically swapped to replace the failed disk. Continuous, redundant data protection is provided, even if a disk fails.

Warm plug service lets you replace one or more disks without powering down the system and the disk array, or rebooting the system. You can obtain warm plug service if multiple disk arrays are configured.

Using the SPARCstorage Array subsystem can improve NFS performance because its processor manages and schedules disk I/O.

The SPARCstorage Manager software is provided with the disk array and provides similar functionality to Online: Disk Suite software. Since there are often many more disks to manage in the SPARCstorage Array subsystem, the SPARCstorage Manager software has an intuitive GUI interface.

Sun StorEdge A1000 RAID Disk Array

The Sun StorEdge A1000 unit is a RAID controller-based configuration. It is designed as a RAID solution for workgroup servers and contains the following:

- RAID controller module
- Two power supplies(hot swappable)
- Battery
- Dual cooling fans (hot swappable)
- Up to twelve disk drives (hot swappable)

The RAID Manager controller module provides disk array management services. It supports dual SCSI hosts on a 16-bit SCSI-2 bus. The two SCSI controllers inside the controller module manage data distribution and storage for up to twelve disk drives. The controllers also perform system status and fault detection functions.

The RAID Manager software allows you to reset the disk array in different RAID configurations

FIGURE 2-11shows a front view of a twelve drive system.

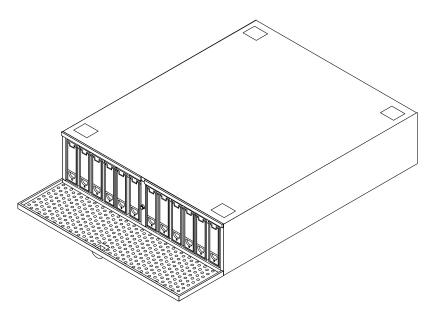

FIGURE 2-11 Sun StorEdge A1000 Front View of a Twelve Drive System

Sun StorEdge A3000 Subsystem

The Sun StorEdge A3000 subsystem is a redundant array of inexpensive disks (RAID) product. It is offered as a companion unit for the following systems:

- SPARCserver 1000
- SPARCcenter 2000
- Sun Enterprise 3x00, 4x00, 5x00, and 6x00
- Sun Enterprise 450 and 250

It is a high performance rack-mounted disk array controller that features redundant power and cooling by incorporating hot-plug technology to support the unexpected loss of one controller, one fan, or one power supply. Failed disk driver can be hot-plugged without stopping I/O activity to the subsystem.

The controller module, which is installed in the subsystem, supports dual SCSI hosts on a 16-bit SCSI-2 bus. In addition, the unit provides the same SCSI-2 bus interface for up to five differential drive trays in the expansion cabinet.

There are two SCSI controllers inside the controller module that use five independent drive channels to manage data distribution and storage for up to thirty-five disk drives. The controllers perform system status and fault detection functions as well.

The controller module combines disk array technology with redundant modular components to provide fast data transfer rates, plus reliable, high-volume data retrieval and storage functions across multiple drives. It works with the RAID Manager software, a disk array management program for configuring, monitoring, and troubleshooting the disk array and provides high-performance disk array management services.

As part of this overall disk management system, the controller module supports the following disk array elements and configurations:

- RAID levels 0 (disk striping), 1 (disk mirroring), 0+1 (disk striping plug disk mirroring), 3 (data and parity are striped across a drive group), and 5 (hot spares)
- Redundant, dual-active controller configurations
- Hot swapable components (controllers, fans, and so on)
- Fast write cache

With RAID 3, data and parity are striped across a drive group. One drive is used for redundancy. All other drives are available for storing user data. FIGURE 2-12 shows a front view of the Sun StorEdge A3000 subsystem.

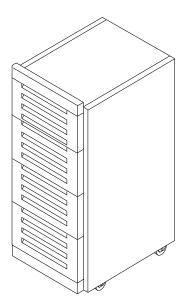

FIGURE 2-12 Front View of the Sun StorEdge A3000 Subsystem

Sun StorEdge A5000 Subsystem

This high-performance and high-availability storage subsystem is designed for the Sun Enterprise 3x00, 4x00, 5x00, and 6x00 family of servers. It replaces the SPARCstorage Array. This subsystem uses 100 Mbit/second Fibre Channel Arbitrated Loop (FC-AL) to create disk arrays that offer two to four times the performance of SCSI-based disk arrays.

The hardware features of this product are:

- 100 Mbit/second PCI and FC-AL host adapters
- Fully redundant hardware drive chassis for rack and tabletop configurations supporting 1.6-inch and 1-inch disk drives
- Optional FC-AL hub

The software features of this product are:

- Volume manager with RAID support
- I/O driver for the FC-AL host adapter
- Solstice SyMON and SNMP support
- Management GUI

This subsystem can store up to 112 Gbytes of information (using 1.6-inch disk drives) or 88 Gbytes of information (using 1-inch disk drives). You can attach up to four disk enclosures using one host adapter. The components in the enclosure are redundant and can be replaced while the subsystem is operating.

FIGURE 2-13 shows a front view of the array.

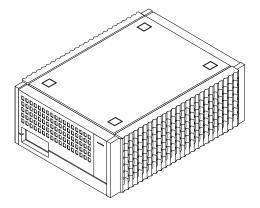

FIGURE 2-13 Front View of the Sun StorEdge A5000 Subsystem

Sun StorEdge A7000 Intelligent Storage Server

The Sun StorEdge A7000 Intelligent Storage Server is a mainframe-class disk array system containing nearly 3 Terrabytes of disk storage. It is designed for the Sun Enterprise 6000 or 6500 data center system. The system contains Symmetric Multiprocessor (SMP) nodes as storage processors. The DataShare software, which runs on this disk array, permits both mainframe and open systems' hosts to directly share the data on the same data volume.

Hardware features of this disk array include fully redundant hardware controllers, cache, hot-pluggable disks, fans, power, and power cords.

Software features include configurable RAID levels, self-diagnostics, health-monitoring, environmental-monitoring, and performance-monitoring.

Serviceablity features include automatic "phone home" and problem reporting supports by on-line diagnostics and repair capability.

Sun StorEdge MultiPack

The Sun StorEdge MultiPack™ enclosure, which is Fast Wide SCSI, can adapt to 50-pin or narrow hosts. It is self-terminating but it can be chained with units that require external termination.

The Sun StorEdge MultiPack uses single connector disks and it is hot plugable. The enclosure can either contain from two to six 1.5-inch disk drives or from two to twelve 1-inch disk drives. To accommodate from two to twelve 1-inch disk drives you must use an SBus SCSI host adapter.

This unit is an excellent RAID solution for desktop servers when you use the unit with Sun StorEdge Volume Manager™ or Solstice™ DiskSuite™. You can also use the Sun StorEdge MultiPack with the Netra NFS server for fast and reliable network attached storage.

FIGURE 2-14shows a front view of the Sun StorEdge MultiPack

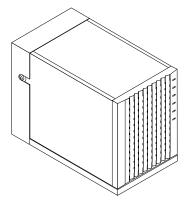

FIGURE 2-14 Front View of the Sun StorEdge MultiPack

Sun StorEdge UniPack

The disk model of the Sun StorEdge UniPack™ enclosure (FIGURE 2-15) contains a self terminating hard disk drive. Models containing a tape drive or a CD-ROM drive are also available. The unit is Fast Wide SCSI.

This expansion unit can be used with the following desktop server systems: SPARCstation 5 system, SPARCstation 10 system, SPARCstation 20 system, Sun Enterprise 1 system, Sun Enterprise 2 system.

This unit can be a very good RAID solution for desktop servers when used with Sun StorEdge Volume Manager™ or Solstice™ DiskSuite™. You can also use this unit with the Netra NFS server for fast and reliable network attached storage.

FIGURE 2-15 shows a front view of the unit.

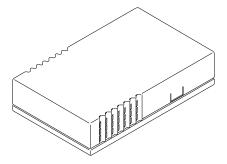

FIGURE 2-15 Sun StorEdge UniPack

Analyzing NFS Performance

This chapter explains how to analyze NFS performance and describes the general steps for tuning your system. This chapter also describes how to verify the performance of the network, server, and each client.

Tuning the NFS Server

When you first set up the NFS server, you need to tune it for optimal performance. Later, in response to a particular problem, you need to tune the server again to optimize performance.

Optimizing Performance

Follow these steps in sequence to improve the performance of your NFS server.

- 1. Measure the current level of performance for the network, server, and each client. See "Checking Network, Server, and Client Performance" later in this chapter.
- Analyze the gathered data by graphing it. Look for exceptions, high disk and CPU utilization, and high disk service times. Apply thresholds or performance rules to the data.
- 3. Tune the server. See Chapter 4.
- 4. Repeat Steps 1 through 3 until you achieve the desired performance.

Resolving Performance Problems

Follow these steps in sequence to resolve performance problems with your NFS server.

- 1. Use tools then observe the symptoms to pinpoint the source of the problem.
- 2. Measure the current level of performance for the network, server, and each client. See "Checking Network, Server, and Client Performance."
- Analyze the data gathered by graphing the data. Look for exceptions, high disk and CPU utilization, and high disk service times. Apply thresholds or performance rules to the data.
- 4. Tune the server. See Chapter 4.
- 5. Repeat Steps 1 through 4 until you achieve the desired performance.

Checking Network, Server, and Client Performance

Before you can tune the NFS server, you must check the performance of the network, the NFS server, and each client. The first step is to check the performance of the network. If disks are operating normally, check network usage because a slow server and a slow network look the same to an NFS client.

FIGURE 3-1 illustrates the steps you must follow in sequence to check the network.

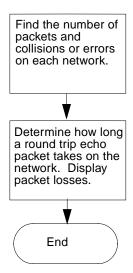

FIGURE 3-1 Flow Diagram for Checking the Network Performance

▼ To Check the Network

1. Find the number of packets, collisions, or errors on each network by typing netstat -i 15.

To look at other interfaces use -I.

% netst	at -i 1	5							
input	le0	out	put	input	(T	otal)	outr	put	
s errs	packet	s errs	colls	packets	errs	packet	ts errs	s co.	lls
31 533	48685	20 0	1078	248181	84 555	1404	49209 1	157	894937
0	43	0	0	238	0	139	0	0	
0	69	0	0	218	0	131	0	2	
0	29	0	0	168	0	94	0	0	
	input s errs 31 533 0	input le0 s errs packets 31 533 48685 0 43 0 69	s errs packets errs 31 533 4868520 0 0 43 0 0 69 0	input le0 output s errs packets errs colls 31 533 4868520 0 1078 0 43 0 0 0 69 0 0	input le0 output input s errs packets errs colls packets 31 533 4868520 0 1078 248181 0 43 0 0 238 0 69 0 0 218	input le0 output input (T s errs packets errs colls packets errs 31 533 4868520 0 1078 24818184 555 0 43 0 0 238 0 0 69 0 0 218 0	input le0 output input (Total) s errs packets errs colls packets errs packet 31 533 4868520 0 1078 24818184 555 140- 0 43 0 0 238 0 139 0 69 0 0 218 0 131	input le0 output input (Total) output s errs packets errs colls packets errs packets errs 131 533 4868520 0 1078 24818184 555 14049209 10 43 0 0 238 0 139 0 0 69 0 0 218 0 131 0	input le0 output input (Total) output s errs packets errs colls packets errs packets errs colls 1533 4868520 0 1078 24818184 555 14049209 157 0 43 0 0 238 0 139 0 0 0 69 0 0 218 0 131 0 2

A description of the arguments to the netstat command follows:

TABLE 3-1 netstat -i 15 Command Arguments

-i Shows the state of the interfaces that are used for TCP/IP traffic

Collects information every 15 seconds

In the netstat -i 15display, a machine with active network traffic should show both input packets and output packets continually increasing.

2. Calculate the network collision rate by dividing the number of output collision counts (Output Colls - le) by the number of output packets (le).

A network-wide collision rate greater than 10 percent can indicate an overloaded network, a poorly configured network, or hardware problems.

3. Calculate the input packet error rate by dividing the number of input errors (le) by the total number of input packets (le).

If the input error rate is high (over 25 percent), the host may be dropping packets.

Transmission problems can be caused by other hardware on the network, as well as heavy traffic and low-level hardware problems. Bridges and routers can drop packets, forcing retransmissions and causing degraded performance.

Bridges also cause delays when they examine packet headers for Ethernet addresses. During these examinations, bridge network interfaces may drop packet fragments.

To compensate for bandwidth-limited network hardware:

- Reduce the packet size specifications.
- Set the read buffer size, rsize, and the write buffer size, wrsize, when using mount or in the /etc/vfstab file. Reduce the appropriate variable(s) (depending on the direction of data passing through the bridge) to 2048. If data passes in both directions through the bridge or other device, reduce both variables:

server:/home /home/server nfs rw,rsize=2048,wsize=2048 0 0

If a lot of read and write requests are dropped and the client is communicating with the server using the User Datagram Protocol (UDP), then the entire packet will be retransmitted, instead of the dropped packets.

4. Determine how long a round trip echo packet takes on the network by typing ping -sRv servername from the client to show the route taken by the packets.

If the round trip takes more than a few milliseconds, there are slow routers on the network, or the network is very busy. Ignore the results from the first ping command. The ping <code>-sRv</code> command also displays packet losses.

The following screen shows the output of the ping <code>-sRv</code> command.

```
client% ping -sRv servername
PING server: 56 data bytes
64 bytes from server (129.145.72.15): icmp_seq=0. time=5. ms
   IP options: <record route> router (129.145.72.1), server
(129.145.72.15), client (129.145.70.114), (End of record)
64 bytes from server (129.145.72.15): icmp_seq=1. time=2. ms
   IP options: <record route> router (129.145.72.1), server
(129.145.72.15), client (129.145.70.114), (End of record)
```

A description of the arguments to the ping command follows:

TABLE 3-2 Arguments to the ping -sRv Command

- s Send option. One datagram is sent per second and one line of output is printed for every echo response it receives. If there is no response, no output is produced.
- Record route option. The Internet Protocol (IP) record option is set so that it stores the route of the packet inside the IP header.
- v Verbose option. CMP packets other than echo response that are received are listed.

If you suspect a physical problem, use ping <code>-sRv</code> to find the response time of several hosts on the network. If the response time (ms) from one host is not what you expect, investigate that host.

The ping command uses the ICMP protocol's echo request datagram to elicit an ICMP echo response from the specified host or network gateway. It can take a long time on a time-shared NFS server to obtain the ICMP echo. The distance from the client to the NFS server is a factor for how long it takes to obtain the ICMP echo from the server.

FIGURE 3-2 shows the possible responses or the lack of response to the ping -sRv command.

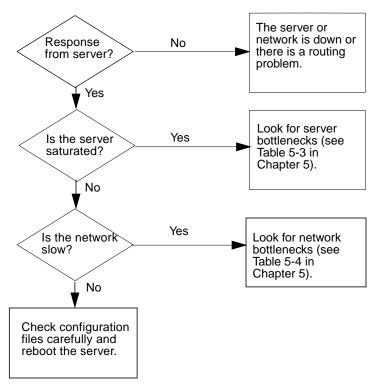

FIGURE 3-2 Flow Diagram of Possible Responses to the ping -sRv Command

Checking the NFS Server

Note – The server used in the following examples is a large SPARCserver 690 configuration.

▼ To Check the NFS Server

1. Determine what is being exported by typing share.

```
server% share
- /export/home rw=netgroup ""
- /var/mail rw=netgroup ""
- /cdrom/solaris_2_3_ab ro ""
```

2. Display the file systems mounted and the disk drive on which the file system is mounted by typing df -k.

If a file system is over 100 percent full, it may cause NFS write errors on the clients.

server% df -k					
Filesystem	kbytes	used	avail	capacity	Mounted on
/dev/dsk/c1t0d0s0	73097	36739	29058	56%	/
/dev/dsk/c1t0d0s3	214638	159948	33230	83%	/usr
/proc	0	0	0	0%	/proc
fd	0	0	0	0%	/dev/fd
swap	501684	32	501652	0%	/tmp
/dev/dsk/c1t0d0s4	582128	302556	267930	53%	/var/mail
/dev/md/dsk/d100	7299223	687386	279377	96%	/export/home
/vol/dev/dsk/c0t6/s	solaris_2_3_	_ab			
	113512	113514	0	100%	/cdrom/solaris_2_3_ab

Note - For this example, the /var/mail and /export/home file systems are used.

Determine on which disk the file systems returned by the ${\tt df}\,$ -k command are stored.

In the previous example, note that /var/mail is stored on /dev/dsk/clt0d0s4 and /export/home is stored on /dev/md/dsk/dl00, an Online: DiskSuiteTM metadisk.

3. Determine the disk number if an Online: DiskSuite metadisk is returned by the df -k command by typing/usr/opt/SUNWmd/sbin/metastat disknumber.

In the previous example, /usr/opt/SUNWmd/sbin/metastat d100 determines what physical disk /dev/md/dsk/d100 uses.

The d100 disk is a mirrored disk. Each mirror is made up of three striped disks of one size concatenated with four striped disks of another size. There is also a hot spare disk. This system uses IPI disks (idX). SCSI disks (sdX) are treated identically.

```
server% /usr/opt/SUNWmd/sbin/metastat d100
d100: metamirror
   Submirror 0: d10
     State: Okay
   Submirror 1: d20

                       Start Block Dbase State
                                                      Hot Spare
   /dev/dsk/c2t1d0s7
                              0
                                    No
                                          Okay
   /dev/dsk/c1t2d0s7
                              0
                                    No
                                          Okay
   /dev/dsk/c2t3d0s7
                                    No
                                          Okay
   Stripe 1: (interlace : 64 blocks)
   Device
                       Start Block Dbase State
                                                      Hot Spare
   /dev/dsk/c4t1d0s7
                              0
                                    No
                                          Okay
   /dev/dsk/c3t2d0s7
                              0
                                    No
                                          Okay
   /dev/dsk/c4t3d0s7
                              0
                                    No
                                          Okay
   /dev/dsk/c3t4d0s7
                            0
                                 No Okay /dev/dsk/c2t4d0s7
```

- 4. Determine the /dev/dsk entries for each exported file system. Use either the whatdev script to find the instance or nickname for the drive or type ls -lL /dev/dsk/clt0d0s4 and more /etc/path_to_inst to find the /dev/dsk entries. An explanation of these steps follows.
- 5. If you will determine the /dev/dsk entries for exported file systems with the whatdev script, follow these steps:
 - a. Type the following whatdev script using a text editor.

```
#!/bin/csh
# print out the drive name - st0 or sd0 - given the /dev entry
# first get something like "/iommu/.../.sd@0,0"
set dev = `/bin/ls -l $1 | nawk '{ n = split($11, a, "/"); split(a[n],b,":");
for(i = 4; i < n; i++) printf("/%s",a[i]); printf("/%s\n", b[1]) }'`
if ( $dev == "" ) exit
# then get the instance number and concatenate with the "sd"
nawk -v dev=$dev '$1 ~ dev { n = split(dev, a, "/"); split(a[n], \
b, "@"); printf("%s%s\n", b[1], $2) }' /etc/path_to_inst</pre>
```

b. Determine the /dev/dsk entry for the file system by typing df / filesystemname.

In this example you would type df /var/mail.

```
furious% df /var/mail
Filesystem kbytes used avail capacity Mounted on
/dev/dsk/c1t0d0s4 582128 302556 267930 53% /var/mail
```

c. Determine the disk number by typing whatdev diskname (the disk name returned by the df /filesystemname command).

In this example you would type whatdev /dev/dsk/clt0d0s4. Disk number id8 is returned, which is IPI disk 8.

```
server% whatdev /dev/dsk/c1t0d0s4
id8
```

- d. Repeat steps b and c for each file system not stored on a metadisk (dev/md/dsk).
- e. If the file system is stored on a meta disk, (dev/md/dsk), look at the metastat output and run the whatdev script on all drives included in the metadisk.

In this example type whatdev /dev/dsk/c2t1d0s7.

There are 14 disks in the /export/home file system. Running the whatdev script on the /dev/dsk/c2t1d0s7 disk, one of the 14 disks comprising the /export/home file system, returns the following display.

```
server% whatdev /dev/dsk/c2t1d0s7
id17
```

Note that /dev/dsk/c2t1d0s7 is disk id17; this is IPI disk 17.

- f. Go to Step 7.
- 6. If you didn't determine the /dev/dsk entries for exported file systems with the whatdev script, you need to identify the /dev/dsk entries for exported file systems with ls -ll. Follow these steps:
 - a. List the drive and its major and minor device numbers by typing ls -ll disknumber.

For example, for the /var/mail file system, type: ls -lL /dev/dsk/clt0d0s4.

```
ls -lL /dev/dsk/c1t0d0s4
brw-r---- 1 root 66, 68 Dec 22 21:51 /dev/dsk/c1t0d0s4
```

b. Locate the minor device number in the ls -1L output.

In the previous screen example, the first number following the file ownership (root), 66, is the major number. The second number, 68, is the minor device number.

- c. Determine the disk number.
- Divide the minor device number, 68 in the previous example, by 8 (68/8 = 8.5).
- Truncate the fraction. The number 8 is the disk number.
- d. Determine the slice (partition) number.

Look at the number following the s (for slice) in the disk number. For example, in /dev/dsk/clt0d0s4, the 4 following the s refers to slice 4.

Now you know that the disk number is 8 and the slice number is 4. This disk is either sd8 (SCSI) or ip8 (IPI).

7. View the disk statistics for each disk by typing iostat -x 15. The -x option supplies extended disk statistics. The 15 means disk statistics are gathered every 15 seconds.

server%										
disk	r/s	w/s	Kr/s	Kw/s	wait	actv	svc t	%w	%b	
id10	0.1	0.2	0.4	1.0	0.0	0.0	24.1	0	1	
id11	0.1	0.2	0.4	0.9	0.0	0.0	24.5	0	1	
id17	0.1	0.2	0.4	1.0	0.0	0.0	31.1	0	1

sd6	0.0	0.0	0.0	0.0	0.0	0.0	109.1	0	0	

Use the iostat -x 15 command to see the disk number for the extended disk statistics. In the next procedure you will use a sed script to translate the disk names into disk numbers.

The output for the extended disk statistics is:

TABLE 3-3 Ouput of the iostat -x 15 Command (Extended Disk Statistics)

r/s	Reads per second
w/s	Writes per second
Kr/s	Kbytes read per second
Kw/s	Kbytes written per second
wait	Average number of transactions waiting for service (queue length)
actv	Average number of transactions actively being serviced

TABLE 3-3 Ouput of the iostat -x 15 Command (Extended Disk Statistics)

```
svc_t Average service time, (milliseconds)

%w Percentage of time the queue is not empty

%b Percentage of time the disk is busy
```

8. Translate disk names into disk numbers

Use iostat and sar. One quick way to do this is to use a sed script:.

a. Type a sed script using a text editor similar to the following d2fs.server sed script.

Your sed script should substitute the file system name for the disk number.

In this example, disk id8 is substituted for /var/mail and disks id9, id10, id11, id17, id18, id19, id25, id26, id27, id28, id33, id34, id35, and id36 are substituted for /export/home.

```
sed `s/id8 /var/mail/
    s/id9 /export/home/
    s/id10 /export/home/
    s/id11 /export/home/
    s/id17 /export/home/
    s/id18 /export/home/
    s/id25 /export/home/
    s/id26 /export/home/
    s/id27 /export/home/
    s/id28 /export/home/
    s/id33 /export/home/
    s/id34 /export/home/
    s/id35 /export/home/
    s/id36 /export/home/
```

b. Run the iostat -xc 15 command through the sed script by typing iostat -xc 15 | d2fs.server.

The options to the previous iostat -xc 15 | d2fs.server command are explained below.

TABLE 3-4 Options to the iostat -xc 15 | d2fs.server Command

-x	Supplies extended disk statistics
-C	Reports the percentage of time the system was in user mode (us), system mode (sy), waiting for I/O (wt), and idling (id)
15	Means disk statistics are gathered every 15 seconds

The following explains the output and headings of the iostat -xc 15 | d2f2.server command.

extended disk			,	cpu									
disk	r/s	w/s	Kr/s			actv	_	%W	%b	us	-		
export/home	0.1	0.2	0.4	1.0	0.0	0.0	24.1	0	1	0	11	2	86
export/home	0.1	0.2	0.4	0.9	0.0	0.0	24.5	0	1				
export/home	0.1	0.2	0.4	1.0	0.0	0.0	31.1	0	1				
export/home	0.1	0.2	0.4	1.0	0.0	0.0	24.6	0	1

The following is a description of the output for the iostat -xc 15 | d2fs.server command.

TABLE 3-5 Output for the iostat -xc 15 Command

disk	Name of disk device
r/s	Average read operations per second
w/s	Average write operations per second
Kr/s	Average Kbytes read per second
Kw/s	Average Kbytes written per second
wait	Number of requests outstanding in the device driver queue
actv	Number of requests active in the disk hardware queue
%W	Occupancy of the wait queue
%b	Occupancy of the active queue—device busy

TABLE 3-5 Output for the iostat -xc 15 Command (Continued)

svc_t Average service time in milliseconds for a complete disk request; includes wait time, active queue time, seek rotation, and transfer latency

us CPU time

sy System time

wt Wait for I/O time

id Idle time

c. Run the sar -d 15 1000 command through the sed script by typing sar -d 15 1000 | d2fs.server.

server%	sar -d 15 1000)	d2fs.server				
12:44:17	device %b	ısy	avque	r+w/s k	olks/s avw	ait a	vserv
12:44:18	export/home	0	0.0	0	0	0.0	0.0
	export/home	0	0.0	0	0	0.0	0.0
	export/home	0	0.0	0	0	0.0	0.0
	export/home	0	0.0	0	0	0.0	0.0
	export/home	0	0.0	0	0	0.0	0.0
	id20	0	0.0	0	0	0.0	0.0
	export/home	0	0.0	0	0	0.0	0.0
	export/home	0	0.0	0	0	0.0	0.0
	export/home	0	0.0	0	0	0.0	0.0
	export/home	0	0.0	0	0	0.0	0.0
	export/home	0	0.0	0	0	0.0	0.0
	export/home	0	0.0	0	0	0.0	0.0
	export/home	0	0.0	0	0	0.0	0.0
	export/home	0	0.0	0	0	0.0	0.0
	var/mail	0	0.0	0	0	0.0	0.0
	export/home	0	0.0	0	0	0.0	0.0
	sd15	7	0.1	4	127	0.0	17.6
	sd16	6	0.1	3	174	0.0	21.6
	sd17	5	0.0	3	127	0.0	15.5

In the sar —d option reports the activities of the disk devices. The 15 means that data is collected every 15 seconds. The 1000 means that data is collected 1000 times. The following terms and abbreviations explain the output.

TABLE 3-6 Output of the sar -d 15 1000 | d2fs.server Command

device	Name of the disk device being monitored
%busy	Percentage of time the device spent servicing a transfer request (same as iostat %b)
avque	Average number of requests outstanding during the monitored period (measured only when the queue was occupied) (same as iostat actv)
r+w/s	Number of read and write transfers to the device, per second (same as iostat $r/s + w/s$)
blks/s	Number of 512-byte blocks transferred to the device, per second (same as iostat $2*(Kr/s + Kw/s)$)
avwait	Average time, in milliseconds, that transfer requests wait in the queue (measured only when the queue is occupied) (iostat wait gives the length of this queue)
avserv	Average time, in milliseconds, for a transfer request to be completed by the device (for disks, this includes seek, rotational latency, and data transfer times)

d. For file systems that are exported via NFS, check the %b/%busy value.

If it is more than 30 percent, check the svc_t value.

The %b value, the percentage of time the disk is busy, is returned by the iostat command. The %busyvalue, the percentage of time the device spent servicing a transfer request, is returned by the sar command. If the %b and the %busy values are greater than 30 percent, go to Step e. Otherwise, go to Step 9.

e. Calculate the svc_t/(avserv + avwait) value.

The svc_t value, the average service time in milliseconds, is returned by the iostat command. The avserv value, the average time (milliseconds) for a transfer request to be completed by the device, is returned by the sar command. Add the avwait to get the same measure as svc_t.

If the <code>svc_t</code> value, the average total service time in milliseconds, is more than 40 ms, the disk is taking a long time to respond. An NFS request with disk I/O will appear to be slow by the NFS clients. The NFS response time should be less than 50 ms on average, to allow for NFS protocol processing and network transmission time. The disk response should be less than 40 ms.

The average service time in milliseconds is a function of the disk. If you have fast disks, the average service time should be less if you have slow disks.

9. Collect data on a regular basis by uncommenting the lines in the user's sys crontab file so that sar collects the data for one month.

Performance data will be continuously collected to provide a history of sar results.

```
root# crontab -l sys
#ident "@(#) sys1.592/07/14 SMI"/* SVr4.0 1.2*/
#
# The sys crontab should be used to do performance collection.
# See cron and performance manual pages for details on startup.
0 * * * 0-6 /usr/lib/sa/sal
20,40 8-17 * * 1-5 /usr/lib/sa/sal
5 18 * * 1-5 /usr/lib/sa/sa2 -s 8:00 -e 18:01 -i 1200 -A
```

Performance data is continuously collected to provide you with a history of sar results.

Note - A few hundred Kbytes will be used at most in /var/adm/sa.

10. Spread the load over the disks.

Stripe the file system over multiple disks if the disks are overloaded using Solstice™ DiskSuite or Online: DiskSuite. Reduce the number of accesses and spread peak access loads out in time using a Prestoserve write cache (see "Using Solstice DiskSuite or Online: DiskSuite to Spread Disk Access Load" on page 70 in Chapter 4.)

- 11. Adjust the buffer cache if you have read-only file systems (see "Adjusting the Buffer Cache (bufhwm)" on page 80 in Chapter 4.
- 12. Display server statistics to identify NFS problems by typing nfsstat -s.

The -s option displays server statistics.

```
server% nfsstat -s
Server rpc:
calls
         badcalls
                  nullrecv
                             badlen
                                       xdrcall
480421
Server nfs:
         badcalls
calls
480421

```

The NFS server display shows the number of NFS calls received (calls) and rejected (badcalls), and the counts and percentages for the various calls that were made. The number and percentage of calls returned by the nfsstat -s command are shown in the following table.

The following terms explain the output of the nfsstat -s command.

TABLE 3-7 Description of the Output of the nfsstat -s Command

calls	Total number of RPC calls received
badcalls	Total number of calls rejected by the RPC layer (the sum of badlen and xdrcall)
nullrecv	Number of times an RPC call was not available when it was thought to be received
badlen	Number of RPC calls with a length shorter than a minimum-sized RPC call
xdrcall	Number of RPC calls whose header could not be XDR decoded

TABLE 3-8 explains the nfsstat -s command output and what actions to take.

TABLE 3-8 Description of the nfsstat -s Command Output

If	Then
writes > 5%**	Install a Prestoserve NFS accelerator (SBus card or NVRAM-NVSIMM) for peak performance. See "Prestoserve NFS Accelerator" on page 76 in Chapter 4.
There are any badcalls	Badcalls are calls rejected by the RPC layer and are the sum of badlen and xdrcall. The network may be overloaded. Identify an overloaded network using network interface statistics.
readlink > 10% of total lookup calls on NFS servers	NFS clients are using excessive symbolic links that are on the file systems exported by the server. Replace the symbolic link with a directory. Mount both the underlying file system and the symbolic link's target on the NFS client. See Step 11.
getattr > 40%	Increase the client attribute cache using the actimeo option. Make sure that the DNLC and inode caches are large. Use vmstat -s to determine the percent hit rate (cache hits) for the DNLC and, if needed, increase ncsize in the /etc/system file. See Step 12 later in this chapter and "Directory Name Lookup Cache (DNLC)" on page 82in Chapter 4

13. Eliminate symbolic links.

If symlink is greater than ten percent in the output of the nfsstat <code>-s</code> command, eliminate symbolic links. In the following example,

/usr/tools/dist/sun4 is a symbolic link for /usr/dist/bin.

a. Type rm /usr/dist/bin to eliminate the symbolic link for /usr/dist/bin.

rm /usr/dist/bin

b. Make /usr/dist/bin a directory by typing mkdir /usr/dist/bin.

mkdir /usr/dist/bin

c. Mount the directories and type the following:

```
client# mount server: /usr/dist/bin
client# mount server: /usr/tools/dist/sun4
client# mount
```

14. View the Directory Name Lookup Cache (DNLC) hit rate by typing vmstat -s. This command returns the hit rate (cache hits).

```
% vmstat -s
... lines omitted
79062 total name lookups (cache hits 94%)
16 toolong
```

a. If the hit rate is less than 90 percent and there is no problem with the number of longnames, increase the ncsize variable in the /etc/system file by typing:

```
set ncsize=5000
```

Directory names less than 30 characters long are cached and names that are too long to be cached are also reported.

The default value of ncsize is: ncsize (name cache) = 17 * maxusers + 90

- For NFS server benchmarks ncsize has been set as high as 16000.
- For maxusers = 2048 ncsize would be set at 34906.

For more information on the Directory Name Lookup Cache, see "Directory Name Lookup Cache (DNLC)" on page 82 in Chapter 4.

- b. Reboot the system.
- 15. Check the system state if the system has a Prestoserve NFS accelerator by typing /usr/sbin/presto. Verify that it is in the UP state.

```
server% /usr/sbin/presto

state = UP, size = 0xfff80 bytes

statistics interval: 1 day, 23:17:50 (170270 seconds)

write cache efficiency: 65%

All 2 batteries are ok
```

■ If it is in the DOWN state, type presto -u.

```
server% presto -u
```

■ If it is in the error state, see the *Prestoserve User's Guide*.

This completes the steps you use to check the server. Continue by checking each client.

Checking Each Client

The overall tuning process must include client tuning. Sometimes, tuning the client yields more improvement than fixing the server. For example, adding 4 Mbytes of memory to each of 100 clients dramatically decreases the load on an NFS server.

▼ To Check Each Client

1. Check the client statistics for NFS problems by typing nfsstat -c at the % prompt.

Look for errors and retransmits.

```
client % nfsstat -c
Client rpc:
calls
         badcalls retrans
                             badxids
                                       timeouts
                                                 waits
                                                           newcreds
384687
                   52
                                       52
badverfs timers
                  toobiq
                                       cantsend bufulocks
                             nomem
Ω
          384
                                                  0
Client nfs:
calls
       badcalls clgets
                             cltoomany
379496
                    379558
Version 2: (379599 calls)
                                                 readlink
        getattr setattr root
                                       lookup
                                                           read
0 0%
         178150 46% 614 0%
                             0 0%
                                       39852 10% 28 0%
                                                           89617 23%
wrcache
         write
                  create
                            remove
                                       rename
                                                 link
                                                           symlink
                           1175 0%
0 0%
         56078 14% 1183 0%
                                       71 0%
                                                 51 0%
                                                           0 0%
mkdir
         rmdir
                   readdir
                             statfs
49 0%
          0 0%
                    987 0%
                             11744 3%
```

The output of the nfsstat -c command shows that there were only 52 retransmits (retrans) and 52 time-outs (timeout) out of 384687 calls.

The $\mbox{nfsstat}$ -c display contains the following fields:

TABLE 3-9 Output of the nfsstat -c Command

calls	Total number of calls sent
badcalls	Total number of calls rejected by RPC
retrans	Total number of retransmissions
badxid	Number of times that a duplicate acknowledgment was received for a single NFS request
timeout	Number of calls that timed out
wait	Number of times a call had to wait because no client handle was available
newcred	Number of times the authentication information had to be refreshed

TABLE 3-9, shown earlier in this chapter, describes the NFS operations. TABLE 3-10 explains the output of the nfsstat -c command and what action to take.

TABLE 3-10 Description of the nfsstat -c Command Output

If	Then			
retrans > 5% of the calls	The requests are not reaching the server.			
badxid is approximately equal to badcalls	The network is slow. Consider installing a faster network or installing subnets.			
badxid is approximately equal to timeouts	Most requests are reaching the server but the server is slower than expected. Watch expected times using $nfsstat -m$.			
badxid is close to 0	The network is dropping requests. Reduce rsize and wsize in the mount options.			
null > 0	A large amount of null calls suggests that the automounter is retrying the mount frequently. The timeout values for the mount are too short. Increase the mount timeout parameter, timeo, on the automounter command line			

The third-party tools you can use for NFS and networks include:

- NetMetrix (Hewlett-Packard)
- SharpShooter (Network General)

2. Display statistics for each NFS mounted file system by typing nfsstat -m.

The statistics include the server name and address, mount flags, current read and write sizes, transmission count, and the timers used for dynamic transmission.

```
client % nfsstat -m
/export/home from server:/export/home
Flags:
vers=2,hard,intr,dynamic,rsize=8192,wsize=8192,retrans=5
Lookups: srtt=10 (25ms), dev=4 (20ms), cur=3 (60ms)
Reads: srtt=9 (22ms), dev=7 (35ms), cur=4 (80ms)
Writes: srtt=7 (17ms), dev=3 (15ms), cur=2 (40ms)
All: srtt=11 (27ms), dev=4 (20ms), cur=3 (60ms)
```

Descriptions of the following terms, used in the output of the ${\tt nfsstat}$ -m command, follow:

TABLE 3-11 Description of the Output of the nfsstat -m Command

srtt	Smoothed round-trip time
dev	Estimated deviation
cur	Current backed-off timeout value

The numbers in parentheses in the previous code example are the actual times in milliseconds. The other values are unscaled values kept by the operating system kernel. You can ignore the unscaled values. Response times are shown for lookups, reads, writes, and a combination of all of these operations (all). TABLE 3-12 shows the appropriate action for the nfsstat -m command.

TABLE 3-12 Results of the nfsstat -m Command

If	Then
srtt > 50 ms	That mount point is slow. Check the network and the server for the disk(s) that provide that mount point. See "To Check the Network" and "To Check the NFS Server" earlier in this chapter.
The message "NFS server not responding" is displayed	Try increasing the timeo parameter in the /etc/vfstab file to eliminate the messages and improve performance. Doubling the initial timeo parameter value is a good baseline.
	After changing the timeo value in the vfstab file, invoke the nfsstat -c command and observe the badxid value returned by the command. Follow the recommendations for the nfsstat -c command earlier in this section.
Lookups: cur > 80 ms	The requests are taking too long to process. This indicates a slow network or a slow server.
Reads: cur > 150 ms	The requests are taking too long to process. This indicates a slow network or a slow server.
Writes: cur > 250 ms	The requests are taking too long to process. This indicates a slow network or a slow server.

Configuring the Server and the Client to Maximize NFS Performance

This chapter provides configuration recommendations to maximize NFS performance. For troubleshooting tips see Chapter 5.

Tuning to Improve NFS Performance

This chapter discusses tuning recommendations for these environments:

- Attribute-intensive environments, in which primarily small files (one to two hundred bytes) are accessed. Software development is an example of an attribute-intensive environment.
- Data-intensive environments, in which primarily large files are accessed. A large file can be defined as a file that takes one or more seconds to transfer (roughly 1 Mbyte). CAD or CAE are examples of data-intensive environments.

Check these items when tuning the system:

- Networks
- Disk drives
- Central processor units
- Memory
- Swap space
- Number of NFS threads in /etc/init.d/nfs.server
- /etc/system to modify kernel variables

Once you have profiled the performance capabilities of your server, begin tuning the system. Tuning an NFS server requires a basic understanding of how networks, disk drives, CPUs, and memory affect performance. To tune the system, determine which parameters need adjusting to improve balance.

▼ To Monitor and Tune Server Performance

- 1. Collect statistics. See Chapter 3.
- **2. Identify a constraint or overutilized resource and reconfigure around it.** Refer to this chapter and Chapter 3 for tuning recommendations.
- 3. Measure the performance gain over a long evaluation period.

Balancing NFS Server Workload

All NFS processing takes place inside the operating system kernel at a higher priority than user-level tasks.

Note – Do not combine databases or time-shared loads on an NFS server because when the NFS load is high any additional tasks performed by an NFS server will run slowly.

Non-interactive workloads such as mail delivery and printing, excluding the SPARCprinter (not supported in the Solaris 2.6 and later releases of the Solaris operating environment) or other Sun printers based on the NeWSprintTM software are good candidates for using the server for dual purpose (such as NFS and other tasks). If you have spare CPU power and a light NFS load, then interactive work will run normally.

Networking Requirements

Providing sufficient network bandwidth and availability is the most important configuration for NFS servers. This means that you should configure the appropriate number and type of networks and interfaces.

Follow these tips when setting up and configuring the network.

- Make sure that network traffic is well balanced across all client networks and that networks are not overloaded.
- If one client network is excessively loaded, watch the NFS traffic on that segment.
- 1. Identify the hosts that are making the largest demands on the servers.
- 2. Partition the work load or move clients from one segment to another.

Simply adding disks to a system does not improve its NFS performance unless the system is truly disk I/O-bound. The network itself is likely to be the constraint as the file server increases in size, requiring the addition of more network interfaces to keep the system in balance.

Instead of attempting to move more data blocks over a single network, consider characterizing the amount of data consumed by a typical client and balance the NFS reads and writes over multiple networks.

Data-Intensive Applications

Data-intensive applications demand relatively few networks. However, the networks must be of high-bandwidth.

If your configuration has either of the following characteristics, then your applications require high-speed networking:

- Your clients require aggregate data rates of more than 1 Mbyte per second.
- More than one client must be able to simultaneously consume 1 Mbyte per second of network bandwidth.

Configuring the Network When the Primary Application of Your Server Is Data-Intensive

■ Configure FDDI, SunATMTM, or another high-speed network.

If fiber cabling can't be used for logistical reasons, consider FDDI, CDDI, or SunFastEthernetTM over twisted-pair implementations. SunATM uses the same size fiber cabling as FDDI. For more information on FDDI, see the *FDDI/S3.0 User's Guide*.

 Configure one FDDI ring for each five to seven concurrent fully NFS-active clients.

Few data-intensive applications make continuous NFS demands. In typical data-intensive EDA and earth-resources applications, this results in 25-40 clients per ring.

A typical use consists of loading a big block of data that is manipulated then written back to the server. Because the data is written back, these environments can have very high write percentages.

 If your installation has Ethernet cabling, configure one Ethernet for every two active clients.

This almost always requires a SPARCserver 1000, SPARCserver 1000E, SPARCcenter 2000, SPARCcenter 2000E system, or an Ultra Enterprise 3000, 4000, 5000, or 6000 system since useful communities require many networks. Configure a maximum of four to six clients per network.

Attribute-Intensive Applications

In contrast, most attribute-intensive applications are easily handled with less expensive networks. However, attribute-intensive applications require many networks. Use lower-speed networking media, such as Ethernet or Token Ring.

To configure networking when the primary application of the server is attributeintensive:

- Configure on Ethernet or Token Ring.
- Configure one Ethernet network for eight to ten fully active clients.

More than 20 to 25 clients per Ethernet results in severe degradation when many clients are active. As a check, an Ethernet can sustain about 250-300 NFS ops/second on the SPECnfs_097 (LADDIS) benchmark, albeit at high collision rates. It is unwise to exceed 200 NFS ops/second on a sustained basis.

■ Configure one Token Ring network for each ten to fifteen active clients.

If necessary, 50 to 80 total clients per network are feasible on Token Ring networks, due to their superior degradation characteristics under heavy load (compared to Ethernet).

Systems with More Than One Class of Users

Mixing network types is not unreasonable. For example, both FDDI and Token Ring are appropriate for a server that supports both a document imaging application (data-intensive) and a group of PCs running a financial analysis application (most likely attribute-intensive).

The platform you choose is often dictated by the type and number of networks, as they may require many network interface cards.

 To configure networking for servers that have more than one class of users, mix network types.

Disk Drives

Disk drive usage is frequently the tightest constraint in an NFS server. Even a sufficiently large memory configuration may not improve performance if the cache cannot be filled quickly enough from the file systems.

Determining if Disks Are the Bottleneck

Use iostat to determine disk usage.

Look at the number of read and write operations per second (see "Checking the NFS Server" on page 42" in Chapter 3).

Because there is little dependence in the stream of NFS requests, the disk activity generated contains large numbers of random access disk operations. The maximum number of random I/O operations per second ranges from 40-90 per disk.

Driving a single disk at more than 60 percent of its random I/O capacity creates a disk bottleneck.

Limiting Disk Bottlenecks

Disk bandwidth on an NFS server has the greatest effect on NFS client performance. Providing sufficient bandwidth and memory for file system caching is crucial to providing the best possible file server performance. Note that read/write latency is also important. For example, each NFSop may involve one or more disk accesses. Disk service times add to the NFSop latency, so slow disks mean a slow NFS server.

Follow these guidelines to ease disk bottlenecks:

Balance the I/O load across all disks on the system.

If one disk is heavily loaded and others are operating at the low end of their capacity, shuffle directories or frequently accessed files to less busy disks.

 Partition the file system(s) on the heavily used disk and spread the file system(s) over several disks.

Adding disks provides additional disk capacity and disk I/O bandwidth.

■ Replicate the file system to provide more network-to-disk bandwidth for the clients if the file system used is read-only by the NFS clients, and contains data that doesn't change constantly.

See the following section, "Replicating File Systems."

 Size the operating system caches correctly, so that frequently needed file system data may be found in memory.

Caches for inodes (file information nodes), file system metadata such as cylinder group information, and name-to-inode translations must be sufficiently large, or additional disk traffic is created on cache misses. For example, if an NFS client opens a file, that operation generates several name-to-inode translations on the NFS server.

If an operation misses the Directory Name Lookup Cache (DNLC), the server must search the disk-based directory entries to locate the appropriate entry name. What would nominally be a memory-based operation degrades into several disk operations. Also, cached pages will not be associated with the file.

Replicating File Systems

Commonly used file systems, such as the following, are frequently the most heavily used file systems on an NFS server:

- /usr directory for diskless clients
- Local tools and libraries
- Third-party packages
- Read-only source code archives

The best way to improve performance for these file systems is to replicate them. One NFS server is limited by disk bandwidth when handling requests for only one file system. Replicating the data increases the size of the aggregate "pipe" from NFS clients to the data. However, replication is *not* a viable strategy for improving performance with writable data, such as a file system of home directories. Use replication with read-only data.

To replicate file systems, do the following:

- Identify the file or file systems to be replicated.
- If several individual files are candidates, consider merging them in a single file system. The potential decrease in performance that arises from combining heavily used files on one disk is more than offset by performance gains through replication.
- Use nfswatch, to identify the most commonly used files and file systems in a group of NFS servers. TABLE A-1 in Appendix Alists performance monitoring tools, including nfswatch, and explains how to obtain nfswatch.
- Determine how clients will choose a replica.

Specify a server name in the /etc/vfstab file to create a permanent binding from NFS client to the server. Alternatively, listing all server names in an automounter map entry allows completely dynamic binding, but may also lead to a client imbalance on some NFS servers. Enforcing "workgroup" partitions in which groups of clients have their own replicated NFS server strikes a middle ground between the extremes and often provides the most predictable performance.

• Choose an update schedule and method for distributing the new data.

The frequency of change of the read-only data determines the schedule and the method for distributing the new data. File systems that undergo a complete change in contents, for example, a flat file with historical data that is updated monthly, can be best handled by copying data from the distribution media on each machine, or using a combination of ufsdump and restore. File systems with few changes can be handled using management tools such as rdist.

■ Evaluate what penalties, if any, are involved if users access old data on a replica that is not current. One possible way of doing this is with the Solaris 2.x JumpStartTM facilities in combination with cron.

Adding the Cache File System

The cache file system is client-centered. You use the cache file system on the client to reduce server load. With the cache file system, files are obtained from the server, block by block. The files are sent to the memory of the client and manipulated directly. Data is written back to the disk of the server.

Adding the cache file system to client mounts provides a local replica for each client. The /etc/vfstab entry for the cache file system looks like this:

```
# device device mount FS fsck mount mount
# to mount to fsck point type pass at boot options
server:/usr/dist cache /usr/dist cachefs 3 yes
ro,backfstype=nfs,cachedir=/cache
```

Use the cache file system in situations with file systems that are read mainly, such as application file systems. Also, you should use the cache file system for sharing data across slow networks. Unlike a replicated server, the cache file system can be used with writable file systems, but performance will degrade as the percent of writes climb. If the percent of writes is too high, the cache file system may decrease NFS performance.

You should also consider using the cache file system if your networks are high speed networks interconnected by routers.

If the NFS server is frequently updated, do not use the cache file system because doing so would result in more traffic than operating over NFS.

• To monitor the effectiveness of the cached file systems use the cachefsstat command (available with the Solaris 2.5 and later operating environment).

The syntax of the cachefsstat command is as follows:

```
system# /usr/bin/cachefsstat [-z] path
```

where:

-z initializes statistics. You should execute cachefs -z (superuser only) before executing cachfsstat again to gather statistics on the cache performance. The statistics printed reflect those just before the statistics are reinitialized.

path is the path the cache file system is mounted on. If you do not specify a path, all mounted cache file systems are used.

Without the -z option, you can execute this command as a regular UNIX user. The statistical information supplied by the cachefsstat command includes cache hits and misses, consistency checking, and modification operation:

TABLE 4-1 Statistical Information Supplied by the cachefsstat Command

Output	Description
cache hit rate	Percentage of cache hits over the total number of attempts
	(followed by the actual numbers of hits and misses)
consistency	Number of consistency checks performed. It is followed by
checks	the number that passed and the number that failed.
modifies	Number of modify operations, including writes and creates.

An example of the cachefsstat command is:

```
system% /usr/bin/cachefsstat /home/sam
cache hit rate: 73% (1234 hits, 450 misses)
consistency checks: 700 (650 pass, 50 fail)
modifies: 321
```

In the previous example, the cache hit rate for the file system should be higher than thirty percent. If the cache hit rate is lower than thirty percent, this means that the access pattern on the file system is widely randomized or that the cache is too small.

The output for a consistency check means that the cache file system checks with the server to see if data is still valid. A high failure rate (15 to 20 percent) means that the data of interest is rapidly changing. The cache may be updated more quickly than

what is appropriate for a cached file system. When you use the output from consistency checks with the number of modifies, you can learn if this client or other clients are making the changes.

The output for modifies is the number of times the client has written changes to the file system. This output is another method to understand why the hit rate may be low. A high rate of modify operations likely goes along with a high number of consistency checks and a lower hit rate.

Also available, beginning with the Solaris 2.5 software environment, are the commands cachefswssize, which determine the working set size for the cache file system and cachefsstat, which displays where the cache file system statistics are being logged. Use these commands to determine if the cache file system is appropriate and valuable for your installation.

Configuration Rules for Disk Drives

Follow these general guidelines for configuring disk drives. In addition to the following general guidelines, more specific guidelines for configuring disk drives in data-intensive environments and attribute-intensive environments follows:

- Configure additional drives on each host adapter without degrading performance (as long as the number of active drives does not exceed SCSI standard guidelines).
- Use Online: DiskSuite or Solstice DiskSuite to spread disk access load across many disks. See "Using Solstice DiskSuite or Online: DiskSuite to Spread Disk Access Load" later in this chapter.
- Use the fastest zones of the disk when possible. See "Using the Optimum Zones of the Disk" later in this chapter.

Keep these rules in mind when configuring disk drives in data-intensive environments:

- Configure for a sequential environment.
- Use disks with the fastest transfer speeds (preferably in stripes).
- Configure one RAID device (logical volume or metadisk) for every three active version 3 clients or one device for every four to five version 2 clients.
- Configure one drive for every client on Ethernet or Token Ring.

When configuring disk drives in attribute-intensive environments:

- Configure with a larger number of smaller disks, which are connected to a moderate number of SCSI host adapters (such as a disk array).
- Configure four to five (or up to eight or nine) fully active disks per fast SCSI host adapter Using smaller disk drives is much better than operating with one large disk drive.

- Configure at least one disk drive for every two fully active clients (on any type of network.)
- Configure no more than eight to ten fully active disk drives for each fast/wide SCSI host adapter.

Using Solstice DiskSuite or Online: DiskSuite to Spread Disk Access Load

A common problem in NFS servers is poor load balancing across disk drives and disk controllers.

To balance loads, do the following:

Balance loads by physical usage instead of logical usage. Use Solstice DiskSuite
or Online: DiskSuite to spread disk access across disk drives transparently by
using its striping and mirroring functions.

The disk mirroring feature of Solstice DiskSuite or Online: DiskSuite improves disk access time and reduces disk usage by providing access to two or three copies of the same data. This is particularly true in environments dominated by read operations. Write operations are normally slower on a mirrored disk since two or three writes must be accomplished for each logical operation requested.

- Balance loads using disk concatenation when disks are relatively full. This
 procedure accomplishes a minimum amount of load balancing
- If your environment is data-intensive, stripe the disk with a small interlace to improve disk throughput and distribute the service load. Disk striping improves read and write performance for serial applications. Use 64 Kbytes per number of disks in the stripe as a starting point for interlace size.
- If your environment is attribute-intensive, where random access dominates disk usage, stripe the disk with the default interlace (one disk cylinder).
- Use the iostat and sar commands to report disk drive usage.

Attaining even disk usage usually requires some iterations of monitoring and data reorganization. In addition, usage patterns change over time. A data layout that works when installed may perform poorly a year later. For more information on checking disk drive usage, see "Checking the NFS Server" on page 42 in Chapter 3.

Using Log-Based File Systems With Solstice DiskSuite or Online: DiskSuite 3.0

The Solaris 2.4 through Solaris 7 software environments and the Online: Disk Suite 3.0 or Solstice DiskSuite software support a log-based extension to the standard UNIX file system, which works like a disk-based Prestoserve NFS accelerator.

In addition to the main file system disk, a small (typically 10 Mbytes) section of disk is used as a sequential log for writes. This speeds up the same kind of operations as a Prestoserve NFS accelerator with two advantages:

- In dual-machine high-available configurations, the Prestoserve NFS accelerator cannot be used. The log can be shared so that it can be used.
- After an operating system crash, the fsck of the log-based file system involves a sequential read of the log only. The sequential read of the log is almost instantaneous, even on very large file systems.

Note – You cannot use the Prestoserve NFS accelerator and the log on the same file system.

Using the Optimum Zones of the Disk

When you analyze your disk data layout, consider zone bit recording.

All of Sun's current disks (except the 207 Mbyte disk) use this type of encoding which uses the peculiar geometric properties of a spinning disk to pack more data into the parts of the platter closest to its edge. This results in the lower disk addresses (corresponding to the outside cylinders) usually outperforming the inside addresses by 50 percent.

• Put the data in the lowest-numbered cylinders.

The zone bit recording data layout makes those cylinders the fastest ones.

This margin is most often realized in serial transfer performance, but also affects random access I/O. Data on the outside cylinders (zero) not only moves past the read/write heads more quickly, but the cylinders are also larger. Data will be spread over fewer large cylinders, resulting in fewer and shorter seeks.

Central Processor Units

This section explains how to determine CPU usage and provides guidelines for configuring CPUs in NFS servers.

Determining CPU Usage

• To get 30 second averages, type mpstat 30 at the % prompt. The following screen is displayed:

system% mpstat 30															
CPU	minf	mjf	xcal	intr	ithr	csw	icsw	migr	smtx	srw	syscl	usr	sys	wt	idl
0	6	0	0	114	14	25	0	6	3	0	48	1	2	25	72
1	6	0	0	86	85	50	0	6	3	0	66	1	4	24	71
2	7	0	0	42	42	31	0	6	3	0	54	1	3	24	72
3	8	0	0	0	0	33	0	6	4	0	54	1	3	24	72

The mpstat 30 command reports statistics per processor. Each row of the table represents the activity of one processor. The first table summarizes all activities since the system was last booted. Each subsequent table summarizes activity for the preceding interval. All values are rates (events per second).

Review the following data in the mpstat output (see Table 4-2):

 TABLE 4-2
 Ouput of the mpstat Command

usr	Percent user time
sys	Percent system time (can be caused by NFS processing)
wt	Percent wait time (treat as for idle time)
idl	Percent idle time

If sys is greater than 50 percent, increase CPU power to improve NFS performance.

Table 4-2 describes guidelines for configuring CPUs in NFS servers.

TABLE 4-3 Guidelines for Configuring CPUs in NFS Servers

If	Then
Your environment is predominantly attribute-intensive, and you have one to three medium-speed Ethernet or Token Ring networks.	A uniprocessor system is sufficient. For smaller systems, the UltraServer 1, SPARCserver 2, or SPARCserver 5 systems have sufficient processor power.
Your environment is predominantly attribute-intensive and you have between 4 to 60 medium-speed Ethernet or Token Ring networks.	Use an UltraServer 2, SPARCserver 10, or SPARCserver 20 system.
You have larger attribute-intensive environments and SBus and disk expansion capacity is sufficient.	Use multiprocessor models of the UltraServer 2, SPARCserver 10 or the SPARCserver 20 systems.
You have larger attribute-intensive environments.	Use dual-processor systems such as: - SPARCserver 10 system Model 512 - SPARCserver 20 system - SPARCserver 1000 or 1000E system - Ultra Enterprise 3000, 4000, 5000, or 6000 system - SPARCcenter 2000/2000E system Either the 40 MHz/1Mbyte or the 50MHz/2 Mbyte module work well for an NFS work load in the SPARCcenter 2000 system. You will get better performance from the 50 MHz/2Mbyte module.
Your environment is data-intensive and you have a high-speed network.	Configure one SuperSPARC processor per high-speed network (such as FDDI).
Your environment is data-intensive and you must use an Ethernet connection due to cabling restrictions.	Configure one SuperSPARC processor for every four Ethernet or Token Ring networks.
Your environment is a pure NFS installation.	You do not need to configure additional processors beyond the recommended number on your server(s).
Your servers perform tasks in addition to NFS processing.	Add additional processors to increase performance significantly.

Memory

Since NFS is a disk I/O-intensive service, a slow server can suffer from I/O bottlenecks. Adding memory eliminates the I/O bottleneck by increasing the file system cache size.

The system could be waiting for file system pages, or it may be paging process images to and from the swap device. The latter effect is only a problem if additional services are provided by the system, since NFS service runs entirely in the operating system kernel.

If the swap device is not showing any I/O activity, then all paging is due to file I/O operations from NFS reads, writes, attributes, and lookups.

Determining if an NFS Server Is Memory Bound

Paging file system data from the disk into memory is a more common NFS server performance problem.

▼ To Determine if the Server Is Memory Bound

1. Watch the scan rate reported by vmstat 30.

If the scan rate (sr, the number of pages scanned) is often over 200 pages/second, then the system is short of memory (RAM). The system is trying to find unused pages to be reused and may be reusing pages that should be cached for rereading by NFS clients.

2. Add memory.

Adding memory eliminates repeated reads of the same data and enables the NFS requests to be satisfied out of the page cache of the server. To calculate the memory required for your NFS server, see "Calculating Memory," which follows.

The memory capacity required for optimal performance depends on the average working set size of files used on that server. The memory acts as a cache for recently read files. The most efficient cache matches the current working set size as closely as possible.

Because of this memory caching feature, it is not unusual for the free memory in NFS servers to be between 0.5 Mbytes to 1.0 Mbytes if the server has been active for a long time. Such activity is normal and desirable. Having enough memory allows you to service multiple requests without blocking.

The actual files in the working set may change over time. However, the size of the working set may remain relatively constant. NFS creates a *sliding window* of active files, with many files entering and leaving the working set throughout a typical monitoring period.

Calculating Memory

You can calculate memory according to general or specific memory rules.

General Memory Rules

Follow these general guidelines to calculate the amount of memory you will need.

- Virtual memory = RAM (main memory) + swap space
- Calculate the amount of memory according to the five-minute rule:

Memory is sized at 16 Mbytes plus memory to cache the data, which will be accessed more often than once in five minutes.

Specific Memory Rules

Follow these specific guidelines to calculate the amount of memory you will need.

 If your server primarily provides user data for many clients, configure relatively minimal memory.

For small installations, this will be 32 Mbytes; for large installations, this will be about 128 Mbytes. In multiprocessor configurations, provide at least 64 Mbytes per processor. Attribute-intensive applications normally benefit slightly more from memory than data-intensive applications.

■ If your server normally provides temporary file space for applications that use those files heavily, configure your server memory to about 75 percent of the size of the active temporary files in use on the server.

For example, if each client's temporary file is about 5 Mbytes, and the server is expected to handle 20 fully active clients, configure it as follows:

(20 clients x 5 Mbytes)/75% = 133 Mbytes of memory

Note that 128 Mbytes is the most appropriate amount of memory that is easily configured.

■ If the primary task of your server is to provide only executable images, configure server memory to be equal to approximately the combined size of the heavily-used binary files (including libraries).

For example, a server expected to provide /usr/openwin should have enough memory to cache the X server, CommandTool, libX11.so, libview.so and libXt. This NFS application is considerably different from the more typical /home, /src, or /data server in that it normally provides the same files repeatedly to all of its clients and is hence able to effectively cache this data. Clients will not use every page of all of the binaries, which is why it is reasonable to

configure only enough to hold the frequently-used programs and libraries. Use the cache file system on the client, if possible, to reduce the load and RAM needs on the server.

If the clients are DOS PCs or Macintosh machines, add more RAM cache on the Sun NFS server; these systems do much less caching than UNIX system clients.

Swap Space

Swap space is almost not needed because NFS servers do not run user processes.

▼ To Set Up Swap Space

- 1. Configure at least 64 Mbytes virtual memory, which is RAM plus swap space (see Table 4-3).
- 2. Set up fifty percent of main memory as an emergency swap space to save a crash dump in case of a system panic.

TABLE 4-4 Swap Space Requirements

Amount of RAM	Swap Space Requirements
16 Mbytes	48 Mbytes
32 Mbytes	32 Mbytes
64 or more Mbytes	None

Prestoserve NFS Accelerator

Note − NFS version 3 reduces the need for Prestoserve[™] capability. Using the Prestoserve NFS accelerator makes a significant difference with NFS version 2. The Prestoserve NFS accelerator makes only a slight improvement with NFS version 3.

Adding a Prestoserve NFS accelerator with NFS version 2 is another way to improve NFS performance. NFS version 2 requires all writes to be written to stable storage before responding to the operation. The Prestoserve NFS accelerator enables high-speed NVRAM instead of slow disks to meet the stable storage requirement.

Two types of NVRAM used by the Prestoserve NFS accelerator are:

- NVRAM-NVSIMM
- SBus

Both types of Prestoserve NFS accelerators speed up NFS server performance by:

- Providing faster selection of file systems
- Caching writes for synchronous I/O operations
- Intercepting synchronous write requests to disk and storing the data in nonvolatile memory

NVRAM-NVSIMM

If you can use either NVRAM hardware, use the NVRAM-NVSIMM for the Prestoserve cache. The NVRAM-NVSIMM and SBus hardware are functionally identical. However, the NVRAM-NVSIMM hardware is slightly more efficient and does not require an SBus slot. The NVRAM-NVSIMMs reside in memory and the NVRAM-NVSIMM cache is larger than the SBus hardware.

The NVRAM-NVSIMM Prestoserve NFS accelerator significantly improves the response time of NFS clients with heavily loaded or I/O-bound servers. To improve performance add the NVRAM-NVSIMM Prestoserve NFS accelerator to the following platforms:

- SPARCserver 20 system
- SPARCserver 1000 or 1000E system
- SPARCcenter 2000 or 2000E system

You can use an alternate method for improving NFS performance in Sun Enterprise 3x00, 4x00, 5x00, and 6x00 systems. This method is to upgrade NVRAM in the SPARCstorage Array that is connected to the server.

Sun Enterprise 3x00, 4x00, 5x00, and 6x00 server systems enable SPARCstorage Array NVRAM fast writes. Turn on fast writes by invoking the ssaadm command.

NVRAM SBus

The SBus Prestoserve NFS accelerator contains only a 1 Mbyte cache and resides on the SBus. You can add the SBus Prestoserve NFS accelerator to any SBus-based server except the SPARCserver 1000(E) system, the SPARCcenter 2000(E), or the Sun Enterprise 3x00, 4x00, 5x00, or 6x00 server systems.

Some systems on which you can add the SBus Prestoserve NFS accelerator are:

■ SPARCserver 5 system

- SPARCserver 20 system
- Sun Enterprise 1 system
- Sun Enterprise 2 system
- SPARCserver 600 series

Tuning Parameters

This section describes how to set the number of NFS threads. It also covers tuning the main NFS performance-related parameters in the /etc/system file. Tune these /etc/system parameters carefully, considering the physical memory size of the server and kernel architecture type.

Note – Arbitrary tuning creates major instability problems, including an inability to boot.

Setting the Number of NFS Threads in /etc/init.d/nfs.server

For improved performance, NFS server configurations should set the number of NFS threads. Each thread is capable of processing one NFS request. A larger pool of threads enables the server to handle more NFS requests in parallel. The default setting of 16 in Solaris 2.4 through Solaris 7 software environments results in slower NFS response times. Scale the setting with the number of processors and networks and increase the number of NFS server threads by editing the invocation of nfsd in /etc/init.d/nfs.server:

/usr/lib/nfs/nfsd -a 64

The previous code box specifies that the maximum allocation of demand-based NFS threads is 64.

There are three ways to size the number of NFS threads. Each method results in about the same number of threads if you followed the configuration guidelines in this manual. Extra NFS threads do not cause a problem.

To set the number of NFS threads, take the *maximum* of the following three suggestions:

■ Use 2 NFS threads for each active client process.

A client workstation usually only has one active process. However, a time-shared system that is an NFS client may have many active processes.

■ Use 16 to 32 NFS threads for each CPU.

Use roughly 16 for a SPARCclassic or a SPARCstation 5 system. Use 32 NFS threads for a system with a 60 MHz SuperSPARC processor.

■ Use 16 NFS threads for each 10 Mbits of network capacity.

For example, if you have one SunFDDI™ interface, set the number of threads to 160. With two SunFDDI interfaces, set the thread count to 320, and so on.

Identifying Buffer Sizes and Tuning Variables

The number of fixed-size tables in the kernel has been reduced in each release of the Solaris software environment. Most are now dynamically sized or are linked to the maxusers calculation. Extra tuning to increase the DNLC and inode caches is required for the Solaris 2.4 through Solaris 7 software environments. For Solaris version 2.4 you must tune the pager. Tuning the pager is not necessary for Solaris 2.5, 2.5.1, 2.6, or 7 operating environments.

Using /etc/system to Modify Kernel Variables

The /etc/system file is read by the operating system kernel at start-up. It configures the search path for loadable operating system kernel modules and enables kernel variables to be set. For more information, see the man page for system(4).

Caution — Use the set commands in /etc/system carefully because the commands in /etc/system cause automatic patches of the kernel.

If your machine does not boot and you suspect a problem with /etc/system, use the boot -aoption. With this option, the system prompts (with defaults) for its boot parameters. One of these is the /etc/system configuration file. Either use the name of a backup copy of the original /etc/system file or /dev/null. Fix the file and immediately reboot the system to make sure it is operating correctly.

Adjusting Cache Size: maxusers

The maxusers parameter determines the size of various kernel tables such as the process table. The maxusersparameter is set in the /etc/system file. For example:

```
set maxusers = 200
```

In the Solaris 2.4 through Solaris 7 software environments, maxusers is dynamically sized based upon the amount of RAM configured in the system. The sizing method used formaxusers is:

```
maxusers = Mbytes of RAM configured in the system
```

The number of Mbytes of RAM configured into the system is actually based upon physmem which does not include the 2 Mbytes or so that the kernel uses at boot time. The minimum limit is 8 and the maximum automatic limit is 1024, which corresponds to systems with 1 Gbyte or more of RAM. It can still be set manually in /etc/system but the manual setting is checked and limited to a maximum of 2048. This is a safe level on all kernel architectures, but uses a large amount of operating system kernel memory.

Parameters Derived From maxusers

Table 4-4 describes the default settings for the performance-related inode cache and name cache operating system kernel parameters.

TABLE 4-5 Default Settings for Inode and Name Cache Parameters

Kernel Resource	Variable	Default Setting
Inode cache	ufs_ninode	17 * maxusers + 90
Name cache	ncsize	17 * maxusers + 90

Adjusting the Buffer Cache (bufhwm)

The bufhwm variable, set in the /etc/system file, controls the maximum amount of memory allocated to the buffer cache and is specified in Kbytes. The default value of bufhwm is 0, which allows up to 2 percent of system memory to be used. This can be increased up to 20 percent and may need to be increased to 10 percent for a

dedicated NFS file server with a relatively small memory system. On a larger system, the bufhwm variable may need to be limited to prevent the system from running out of the operating system kernel virtual address space.

The buffer cache is used to cache inode, indirect block, and cylinder group related disk I/O only. The following is an example of a buffer cache (bufhwm) setting in the /etc/system file that can handle up to 10 Mbytes of cache. This is the highest value to which you should set bufhwm.

```
set bufhwm=10240
```

You can monitor the buffer cache using sar -b (see the following code example), which reports a read (%rcache) and a write hit rate (%wcache) for the buffer cache.

```
# sar -b 5 10
SunOS hostname 5.2 Generic sun4c    08/06/93
23:43:39 bread/s lread/s %rcache bwrit/s lwrit/s %wcache pread/s pwrit/s
Average    0    25    100    3    22    88    0    0
```

If a significant number of reads and writes per second occur (greater than 50) and if the read hit rate (%rcache) falls below 90 percent, or if the write hit rate (%wcache) falls below 65 percent, increase the buffer cache size, bufhwm.

In the previous sar -b 5 10 command output, the read hit rate (%rcache) and the write hit rate (%wcache) did not fall below 90 percent or 65 percent respectively.

Following are descriptions of the arguments to the sar command.

 TABLE 4-6
 Descriptions of the Arguments to the sar Command

Checks buffer activity

Time, every 5 seconds (must be at least 5 seconds)

Number of times the command gathers statistics

Your system will prevent you from increasing the buffer cache to an unacceptably high level. Signs of increasing buffer cache size include:

- Hung server
- Device drivers that suffer from a shortage of operating system kernel virtual memory

Directory Name Lookup Cache (DNLC)

Size the directory name lookup cache (DNLC) to a default value using maxusers. A large cache size (ncsize) significantly increases the efficiency of NFS servers with multiple clients.

• To show the DNLC hit rate (cache hits), type vmstat -s.

```
% vmstat -s
... lines omitted
79062 total name lookups (cache hits 94%)
16 toolong
```

Directory names less than 30 characters long are cached and names that are too long to be cached are also reported. A cache miss means that a disk I/O may be needed to read the directory when traversing the path name components to get to a file. A hit rate of less than 90 percent requires attention.

Cache hit rates can significantly affect NFS performance. getattr, setattr, and lookup usually represent greater than 50 percent of all NFS calls. If the requested information isn't in cache, the request will generate a disk operation that results in a performance penalty as significant as that of a read or write request. The only limit to the size of the DNLC cache is available kernel memory.

If the hit rate (cache hits) is less than 90 percent and a problem does not exist with the number of longnames, tune the ncsize variable (see "To Reset ncsize,") which follows. The variable ncsize refers to the size of the DNLC in terms of the number of name and vnode translations that can be cached. Each DNLC entry uses about 50 bytes of extra kernel memory.

▼ To Reset ncsize

• Set ncsize in the /etc/system file to values higher than the default (based on maxusers.)

As an initial guideline, since dedicated NFS servers do not need a lot of RAM, maxusers will be low and the DNLC will be small; double its size.

```
set ncsize=5000
```

The default value of nosize is:

```
ncsize (name cache) = 17 * maxusers + 90
```

■ For NFS server benchmarks, set it as high as 16000.

■ For maxusers = 2048, set it at 34906.

• Reboot the system.

See "Increasing the Inode Cache" which follows.

Increasing the Inode Cache

A memory-resident inode is used whenever an operation is performed on an entity in the file system. The inode read from disk is cached in case it is needed again. ufs_ninode is the size that the UNIX file system attempts to keep the list of idle inodes. You can have ufs_ninod set to 1 but have 10,000 idle inodes. As active inodes become idle, if the number of idle inodes goes over ufs_ninode, then memory is reclaimed by tossing out idle inodes.

Every entry in the DNLC cache points to an entry in the inode cache, so both caches should be sized together. The inode cache should be at least as big as the DNLC cache. For best performance, it should be the same size in the Solaris 2.4 through Solaris 7 operating environments.

Since it is just a limit, ufs_ninode you can tweak with adb on a running system with immediate effect. The only upper limit is the amount of kernel memory used by the inodes. The tested upper limit corresponds to maxusers = 2048, which is the same as nosize at 34906.

To report the size of the kernel memory allocation use sar -k.

- In the Solaris 2.4 operating environment, each inode uses 300 bytes of kernel memory from the lg_mem pool.
- In the Solaris 2.5.1, 2.6, and 7 operating environments, each inode uses 320 bytes of kernel memory from the lg_mem pool. ufs_ninode is automatically adjusted to be at least ncsize. Tune ncsize to get the hit rate up and let the system pick the default ufs_ninodes.

With the Solaris 2.5.1. 2.6, and 7 software environments, ufs_ninode is automatically adjusted to be at least ncsize. Tune ncsize to get the hit rate up and let the system pick the default ufs_ninodes.

Increasing the Inode Cache in the Solaris 2.4 or the 2.5 Operating Environments

If the inode cache hit rate is below 90 percent, or if the DNLC requires tuning for local disk file I/O workloads:

1. Increase the size of the inode cache.

2. Change the variable ufs_ninode in your /etc/system file to the same size as the DNLC (ncsize). For example, for the Solaris version 2.4, type:

set ufs_ninode=5000

The default value of the inode cache is the same as that for ncsize:

ufs_ninode (default value) = 17 * maxusers + 90.

Caution – Do not set ufs_ninode less than ncsize. The ufs_ninode parameter limits the number of inactive inodes, rather than the total number of active and inactive inodes.

Reboot the system.

Increasing Read Throughput

If you are using NFS over a high speed network such as FDDI, SunFastEthernet, or SunATMTM, you will have better read throughput by increasing the number of readaheads on the NFS client.

Increasing read-aheads is *not* recommended under these conditions:

- The client is very short of RAM.
- The network is very busy.
- File accesses are randomly distributed.

When free memory is low, read-ahead will not be performed.

The read-ahead is set to 1 block, by default (8 Kbytes with version 2 and to 32 Kbytes with version 3). For example, a read-ahead set to 2 blocks uses an additional 16 Kbytes from a file while you are reading the first 8 Kbytes from the file. Thus, the read-ahead stays one step ahead of you and uses information in 8 Kbyte increments to stay ahead of the information you need.

Increasing the read-ahead count can improve read throughput up to a point. The optimal read-ahead setting will depend on your configuration and application. Increasing the read-ahead value beyond that setting may actually reduce throughput. In most cases, the optimal read-ahead setting is less than eight read-aheads (8 blocks)..

Note — In the following procedure you can tune the nfs_nra and the nfs3_nra values independently.

If a client is running Solaris the 2.5, 2.5.1, 2.6, or 7 operating environment, the client may need to tune nfs_nra (NFS version 2). This happens if the client is talking to a server that does not support version 3.

▼ To Increase the Number of Read-Aheads With Version 2

1. Add the following line to /etc/system on the NFS client.

```
set nfs:nfs_nra=4
```

2. Reboot the system to implement the read-ahead value.

▼ To Increase the Number of Read-Aheads With Version 3

- 1. Add the following line to /etc/system on the NFS client:
 - With versions of the Solaris software environment before the Solaris 2.6 software environment:

```
set nfs:nfs3_nra=6
```

■ With the Solaris 2.6 operating environment, type:

```
set nfs:nfs3_nra=2
```

■ With the Solaris 7 operating environment type:

```
set nfs:nfs3_nra=4
```

Note — Raising the read-ahead count too high can make read throughput worse. You may consider running benchmarks with different values of nfs3_nra or nfs_nra to see what works best in your environment.

2. Reboot the system to implement the read-ahead value.

Troubleshooting

Troubleshooting Tools

This chapter presents troubleshooting tips for the following types of problems:

- General troubleshooting tuning
- Client bottlenecks
- Server bottlenecks
- Network-related bottlenecks

General Troubleshooting Tuning Tips

This section (see TABLE 5-1) lists the actions to perform when you encounter a tuning problem.

TABLE 5-1 General Troubleshooting Tuning Problems and Actions to Perform

Command/Tool	Command Output/Result	Action
netstat -i	Collis+Ierrs+Oerrs/Ipkts + Opkts > 2%	Check the Ethernet hardware.
netstat -i	Collis/Opkts > 10%	Add an Ethernet interface and distribute the client load.

 TABLE 5-1
 General Troubleshooting Tuning Problems and Actions to Perform

Command/Tool	Command Output/Result	Action
netstat -i	Ierrs/Ipks > 25%	The host may be dropping packets, causing high input error rate. To compensate for bandwidth-limited network hardware: reduce the packet size; set the read buffer size, rsize and/or the write buffer size wsize to 2048 when using mount or in the /etc/vfstab file. See "To Check the Network" on page 39 in Chapter 3.
nfsstat -s	readlink > 10%	Replace symbolic links with mount points.
nfsstat -s	writes > 5%	Install a Prestoserve NFS accelerator (SBus card or NVRAM-NVSIMM) for peak performance. See "Prestoserve NFS Accelerator" on page 76 in Chapter 4.
nfsstat -s	There are any badcalls.	The network may be overloaded. Identify an overloaded network using network interface statistics.
nfsstat -s	getattr > 40%	Increase the client attribute cache using the actimeo option. Make sure the DNLC and inode caches are large. Use vmstat -s to determine the percent hit rate (cache hits) for the DNLC and, if needed, increase ncsize in the /etc/system file. See "Directory Name Lookup Cache (DNLC)" on page 82in Chapter 4.
vmstat -s	Hit rate (cache hits) < 90%	Increase nosize in the /etc/system file.
Ethernet monitor, for example: SunNet Manager™ SharpShooter, NetMetrix	Load > 35%	Add an Ethernet interface and distribute client load.

Client Bottlenecks

This section (see TABLE 5-2) shows potential client bottlenecks and how to remedy them.

TABLE 5-2 Client Bottlenecks

Symptom(s)	Command/Tool	Cause	Solution
NFS server hostname not responding or slow response to commands when using NFS-mounted directories	nfsstat	User's path variable	List directories on local file systems first, critical directories on remote file systems second, and then the rest of the remote file systems.
NFS server hostname not responding or slow response to commands when using NFS-mounted directories	nfsstat	Running executable from an NFS- mounted file system	Copy the application locally (if used often).
NFS server hostname not responding; badxid >5% of total calls and badxid = timeout	nfsstat -rc	Client times out before server responds	Check for server bottleneck. If the server's response time isn't improved, increase the timeo parameter in the /etc/vfstab file of clients. Try increasing timeo to 25, 50, 100, 200 (tenths of seconds). Wait one day between modifications and check to see if the number of time-outs decreases.
badxid = 0	nfsstat -rc	Slow network	Increase rsize and wsize in the /etc/vfstab file. Check interconnection devices (bridges, routers, gateways).

Server Bottlenecks

This section (see TABLE 5-3) shows server bottlenecks and how to remedy them.

TABLE 5-3 Server Bottlenecks

Symptom(s)	Command/Tool	Cause	Solution
NFS server hostname not responding	vmstat -s oriostat	Cache hit rate is < 90%	Adjust the suggested parameters for DNLC, then run to see if the symptom is gone. If not, reset the parameters for DNLC. Adjust the parameters for the buffer cache, then the inode cache, following the same procedure as for the DNLC.
NFS server hostname not responding	netstat -m or nfsstat	Server not keeping up with request arrival rate	Check the network. If the problem is not the network, add appropriate Prestoserve NFS accelerator, or upgrade the server.
High I/O wait time or CPU idle time; slow disk access times or NFS server hostname not responding	iostat -x	I/O load not balanced across disks; the svc_t value is greater than 40 ms	Take a large sample (~2 weeks). Balance the load across disks; add disks as necessary. Add a Prestoserve NFS accelerator for synchronous writes. To reduce disk and network traffic, use tmpfs for /tmp for both server and clients. Measure system cache efficiencies. Balance load across disks; add disks as necessary.
Slow response when accessing remote files	netstat -s or snoop	Ethernet interface dropping packets	If retransmissions are indicated, increase buffer size. For information on how to use snoop, see "snoop" in Appendix A.

Network Bottlenecks

This section (see TABLE 5-4) shows network-related bottlenecks and how to remedy them.

TABLE 5-4 Network-Related Bottlenecks

Symptoms	Command/Tool	Cause	Solution
Poor response time when accessing directories mounted on different subnets or NFS server hostname not responding	netstat -rs	NFS requests being routed	Keep clients on the subnet directly connected to server.
Poor response time when accessing directories mounted on different subnets or NFS server hostname not responding	netstat -s shows incomplete or bad headers, bad data length fields, bad checksums.	Network problems	Check the network hardware.
Poor response time when accessing directories mounted on different subnets or NFS server hostname not responding; sum of input and output packets per second for an interface is over 600 per second	netstat -i	Network overloaded	The network segment is very busy. If this is a recurring problem, consider adding another (1e) network interface.
Network interface collisions are over 120 per second	netstat -i	Network overloaded	Reduce the number of machines on the network or check the network hardware.
Poor response time when accessing directories mounted on different subnets or NFS server hostname not responding	netstat -i	High packet collision rate (Collis/Opkts>.10)	- If packets are corrupted, it may be due to a corrupted MUX box; use the Network General Sniffer product or another protocol analyzer to find the cause Check for overloaded network. If there are too many nodes, create another subnet Check network hardware; could be bad tap, transceiver, hub on 10base-T. Check cable length and termination.

Using NFS Performance-Monitoring and Benchmarking Tools

This appendix discusses tools that help you monitor NFS and network performance. These tools generate information that you can use to tune and improve performance. See Chapter 3, "Analyzing NFS Performance," and Chapter 4, "Configuring the Server and the Client to Maximize NFS Performance."

For more information about these tools, refer to their man pages (where applicable). For third-party tools, refer to the product documentation.

This chapter also describes SPEC SFS 2.0, an NFS file server benchmarking tool.

NFS Monitoring Tools

TABLE A-1 describes the tools that you can use to monitor NFS operations and performance.

 TABLE A-1
 NFS Operations and Performance-Monitoring Tools

Tool	Function	
iostat	Reports I/O statistics, including disk I/O activity	
nfsstat	Reports NFS statistics: NFS and RPC (Remote Procedure Call) interfaces to the kernel; can also be used to initialize statistical information	
nfswatch	Shows NFS transactions classified by file system; nfswatch is a public domain tool with source code available on the URL: http://www.ers.ibm.com/~davy/software/nfswatch.html	
sar	Reports system activity such as CPU utilization, buffer activity, and disk and tape device activity	
SharpShooter*	Pinpoints bottlenecks, balances NFS load across clients and servers; shows effect of distributed applications and balances network traffic across servers; accounts for disk usage by user or group	
vmstat	Reports virtual memory statistics including disk activity	
	* by Network General Corporation, formerly AIM Technology	

For additional networking and network monitoring utilities, see the URL: http://www.alw.nih.gov/Security/prog-network.html

Network Monitoring Tools

Use the tools described in TABLE A-2 to monitor network performance as it relates to NFS.

TABLE A-2 Network Monitoring Tools

Tool	Function
snoop	Displays information about specified packets on Ethernet
netstat	Displays the contents of network-related data structures
ping	Sends ICMP ECHO_REQUEST packets to network hosts
NetMetrix Load Monitor	Handles network load monitoring and characterization of load in terms of time, source, destination, protocol, and packet size
SunNet Manager	Performs network device monitoring and troubleshooting
LAN analyzers: Network General Sniffer, Novell/Excelan Lanalyzer	Performs packet analysis

snoop

The snoop command is part of the Solaris 2.x software environment. The snoop command must run by root (#) to capture packets in promiscuous mode. To capture packets in non-promiscuous mode, or to analyze packets from a captured file, you do not need to be superuser.

In promiscuous mode, the interface turns off its filter, which enables you to see all packets on the subnet, whether or not they are addressed to your system. You can observe other packets not destined for your system. Promiscuous mode is limited to root.

Using the snoop command turns a Sun system into a network sniffer, which can detect network problems. It also captures a certain number of network packets, enables you to trace the calls from each client to each server, and displays the contents of the packets. You can also save the contents of the packets to a file, which you can inspect later.

The snoop command does the following:

- Logs or displays packets selectively
- Provides accurate time stamps for checking network Remote Procedure Call (RPC) response time
- Formats packets and protocol information in a user-friendly manner

The snoop command can display packets in a single-line summary or in expanded form. In summary form, only the data pertaining to the highest level protocol is displayed. For example, an NFS packet will have only NFS information displayed. The underlying RPC, UDP (User Datagram Protocol), IP (Internet Protocol), and network frame information is suppressed, but can be displayed if you choose either of the verbose (-v or -V) options.

The snoop command uses both the packet filter and buffer modules of the Data Link Provider Interface (DLPI) so the packets can be captured efficiently and transmitted to or received from the network.

To view or capture all traffic between any two systems, run snoop on a third system.

The snoop command is a useful tool if you are considering subnetting, since it is a packet analysis tool. You can use the output of the snoop command to drive scripts that accumulate load statistics. The program is capable of breaking the packet header in order to debug it, and to investigate the source of incompatibility problems.

The following shows some examples of how to use snoop.

Looking at Selected Packets in a Capture File (pkts)

The statistics show which client is making a read request, and the left column shows the time in seconds, with a resolution of about 4 microseconds.

When a read or write request is made, be sure the server doesn't time-out. If it does, the client has to re-send again, and the client's IP code will break up the write block into smaller UDP blocks. The default write time is .07 seconds. The time-out factor is a tunable parameter in the mount command.

CODE EXAMPLE A-1 Output of the snoop -i pkts -p99, 108 Command

CODE EXAMPLE A-1 Output of the snoop -i pkts -p99, 108 Command

103	0.0072	viper -> marmot	NFS R LOOKUP No such file
or di	rectory		
104	0.0085	bugbomb -> sunroof	RLOGIN C PORT=1023 h
105	0.0005	kandinsky -> sparky	RSTAT C Get Statistics
106	0.0004	beeblebrox -> sunroof	NFS C GETATTR FH=0307
107	0.0021	sparky -> kandinsky	RSTAT R
108	0.0073	office -> jeremiah	NFS C READ FH=2584 at
40960	for 8192		

The following table describes the arguments to the snoop command.

TABLE A-3 Arguments to the snoop Command

-i pkts	Displays packets previously captured in the pkts file
-p99,108	Selects packets 99 through 108 to be displayed from a capture file; the first number 99, is the first packet to be captured; the last number, 108, is the last packet to be captured; the first packet in a capture file is packet 1

• To get more information on a packet, type:

```
# snoop -i pkts -v 101
```

The command snoop -i pkts -v 101 obtains more detailed information on packet 101. TABLE A-4 describes the command arguments.

TABLE A-4 Description of Arguments to the snoop -i pkts -v 101 Command

-i pkts	Displays packets previously captured in the pkts file
-v	Verbose mode; prints packet headers in detail for packet 101; use this option only when you need information on selected packets

To view NFS packets, type:

```
# snoop -i pkts rpc nfs and sunroof and boutique
1 0.0000 boutique -> sunroof NFS C GETATTR FH=8E6C
2 0.0046 sunroof -> boutique NFS R GETATTR OK
3 0.0080 boutique -> sunroof NFS C RENAME FH=8E6C MTra00192 to .nfs08
```

This example gives a view of the NFS packets between the systems sunroof and boutique. TABLE A-5describes the arguments to the previous snoop command.

TABLE A-5	Arguments to the snoop -i pkts rpc nfs and sunroof and boutique Command
-i pkts	Displays packets previously captured in the pkts file
rpc nfs	Displays packets for an RPC call or reply packet for the NFS protocol; the option following nfs is the name of an RPC protocol from /etc/rpc or a program number
and	Performs a logical and operation between two boolean values; for example, sunroof boutique is the same as sunroof and boutique

• To save packets to a new capture file, type:

snoop -i pkts -o pkts.nfs rpc nfs sunroof boutique

TABLE A-6describes the arguments to the previous snoop command.

TABLE A-6 Description of Arguments to the snoop -i pkts -o.nfs rpc nfs sunroof boutique Command

-i pkts	Displays packets previously captured in the pkts file
-o pkts.nfs	Saves the displayed packets in the pkts.nfs output file
rpc nfs	Displays packets for an RPC call or reply packet for the NFS protocol; the option following nfs is the name of an RPC protocol from /etc/rpc or a program number

See the snoop man page for additional details on options used with the snoop command and additional information about using snoop.

SPEC System File Server 2.0

SPEC System File Server (SFS) 2.0 measures NFS file server throughput and response time. It is a one test benchmark suite consisting of 097.LADDIS. It contains an updated workload that was developed based on a survey of more than 1,000 NFS servers in different application environments. The workload is larger and the

response-time threshold is lower than those used in SFS 1.1, due to advances in server technologies. Because of these and other changes, you cannot compare SPEC SFS 2.0 results to SFS 1.1 or SFS 1 results.

In addition to general code improvements, SPEC SFS 2.0 includes these enhancements

- Measures results for both NFS Version 2 and 3
- Adds support for TCP (either TCP or UDP can be used as the network transport)
- Operation mix more closely matches real-world NFS workloads
- Improved interface to accommodate both accomplished and novice users

Two reference points are considered when reporting 097.LADDIS:

- NFS operation throughput—The peak number of NFS operations the target server can complete in a given number of milliseconds. The larger the number of operations an NFS server can support, the more users it can serve.
- Response time—The average time needed for an NFS client to receive a reply from a target server in response to an NFS request. The response time of an NFS server is the client's perception of how fast the server is.

LADDIS is designed so that its workload can be incrementally increased until the target server performance falls below a certain level. That point is defined as an average response time exceeding 50ms. This restriction is applied when deriving the maximum throughput in NFS operations per second for which the response time does not exceed 50 ms.

If throughput continues to increase with the workload, the throughput figure at 50 ms is reported. In many cases, throughput will start to fall off at a response time below the 50 ms limit. In these cases, the tables in this chapter report the response time at the point of maximum throughput.

0.97 LADDIS Benchmark

The SPEC SFS 2.0 (0.97 LADDIS)benchmark is a synthetic NFS workload based on an application abstraction, an NFS operation mix, and an NFS operation request rate. The workload generated by the benchmark emulates an intensive software development environment at the NFS protocol level. The LADDIS benchmark makes direct RPC calls to the server, eliminating any variation in NFS client implementation. This makes it easier to control the operation mix and workload, especially for comparing results between vendors. However, this also hides the benefits of special client implementations, such as the cache file system client.

TABLE A-7 shows the NFS operations mix. These percentages indicate the relative number of calls made to each operation.

TABLE A-7 NFS Operations Mix by Call

NFS Operation	Percent Mix
Lookup	34
Read	22
Write	15
GetAttr	13
ReadLink	8
ReadDir	3
Create	2
Remove	1
Statfs	1
SetAttr	1

The LADDIS benchmark for NFS file systems uses an operation mix that is 15 percent write operations. If your NFS clients generate only one to two percent write operations, LADDIS underestimates your performance. The greater the similarity between the operation mixes, the more reliable the maximum throughput in NFS operations is as a reference.

Running the benchmark requires the server being benchmarked to have at least two NFS clients (the NFS load generators), and one or more isolated networks. The ability to support multiple networks is important because a single network may become saturated before the server maximum performance point is reached. One client is designated as the LADDIS Prime Load Generator. The Prime Load Generator controls the execution of the LADDIS load generating code on all load-generating clients. It typically controls the benchmark. In this capacity, it is responsible for collecting throughput and response time data at each of the workload points and for generating results.

To improve response time, configure your NFS server with the NVRAM-NVSIMM Prestoserve NFS accelerator. NVSIMMs provide storage directly in the high-speed memory subsystem. Using NVSIMMs results in considerably lower latency and reduces the number of disks required to attain a given level of performance.

Since there are extra data copies in and out of the NVSIMM, the ultimate peak throughput is reduced. Because NFS loads rarely sustain peak throughput, the better response time using the NVSIMMs is preferable. For information on the Prestoserve NFS accelerator, see "Prestoserve NFS Accelerator" on page 76 in Chapter 4.

SPEC SFS 2.0 Results

Sun Microsystems has run SPEC SFS 2.0 benchmarks on the Sun Enterprise 3000-6000 family of servers. The benchmarks were run with NFS Version 2 and NFS Version 3. TABLE A-8 shows the results with Version 2. TABLE A-9 shows the results with Version 3.

TABLE A-8 SPEC SFS 2.0 Results With Version 2

System	Number of CPUs	Result	Overall Response Time
Sun Enterprise 3000	6	11806	5.1
Sun Enterprise 4000	12	20406	6.7
Sun Enterprise 6000	18	25639	9.9

TABLE A-9 SPEC SFS 2.0 Results With Version 3

System	Number of CPUs	Result	Overall Response Time
Sun Enterprise 3000	6	5903	5.4
Sun Enterprise 4000	12	10592	5.6
