# Configuring BGP

This chapter describes how to configure Border Gateway Protocol (BGP). For a complete description of the BGP commands in this chapter, refer to the "BGP Commands" chapter of the *Network Protocols Command Reference, Part 1*. To locate documentation of other commands that appear in this chapter, use the command reference master index or search online.

The Border Gateway Protocol, as defined in RFCs 1163 and 1267, is an Exterior Gateway Protocol (EGP). It allows you to set up an interdomain routing system that provides the loop-free exchange of routing information between autonomous systems.

For protocol-independent features, see the chapter "Configuring IP Routing Protocol-Independent Features" in this document.

# **Cisco's BGP Implementation**

In BGP, each route consists of a reachable destination (network or prefix), a list of autonomous systems that information has passed through (called the *autonomous system path*), and a list of other *path attributes*. We support BGP Versions 2, 3, and 4, as defined in RFCs 1163, 1267, and 1771, respectively.

The autonomous system path is used to ensure loop free paths through the internetwork. The other path attributes are used to enforce autonomous system level policies, such as which exit point to use or which autonomous systems may be used to transit traffic to other autonomous systems. A description of some of the other path attributes available are given in the following paragraphs.

The Multiple Exit Discriminator (MED, also called the INTER\_AS\_METRIC in BGP versions 2 and 3) is used to provide a hint about which entrance point an autonomous system would like other autonomous system to use. When an update is sent to an iBGP peer, the MED is passed along without any change. This action enables all the speakers in the same autonomous system to make a consistent path selection.

The NEXT\_HOP attribute is used to provide the address packets destined to this prefix should be forwarded to. It is, by default, set to the address of the eBGP peer which first advertises this prefix into the autonomous system, and is not changed when the prefix is advertised to iBGP peers. The Cisco IOS software automatically calculates the value for this attribute.

The Local Preference attribute is used by the BGP speakers in an autonomous system to determine the best path out of the autonomous system to a given destination. This attribute is usually set at the autonomous system border using a route map or some other technique.

Transitive, optional path attributes are passed along to other BGP-speaking routers. << Do we need to cover mandatory and optional transitives in more detail or remove this sentence?>>

In addition to the attributes that BGP carries in updates, BGP Version 4 supports classless interdomain routing (CIDR), which lets you reduce the size of your routing tables by creating aggregate routes, resulting in supernets. CIDR eliminates the concept of network classes within BGP and supports the advertising of IP prefixes. CIDR routes can be carried by OSPF, Enhanced IGRP, and ISIS-IP, and RIP version 2.

### How BGP Selects Paths

A router running Cisco IOS Release 12.0 or later does not select or use an iBGP route unless both of the following are true:

- The router has a route available to the next-hop.
- If syncronization is enabled, the router has received syncronized routes from an IGP.

BGP bases it's decision first on whether a path is loop free, then on the polcies indicated by the path attributes along with the policies configured on the router. The following summrized how BGP chooses the best path to a given destination.

- 1 If the next hop is not reachable through an IGP route installed in the routing table, do not consider this prefix for installation in the routing table.
  - If the only route you have to the next hop indicated in the NEXT\_HOP attribute of a prefix is learned through iBGP, the route will oscillate in the routing table. It will be installed by BGP, then removed about 60 seconds later, only to be reinstalled momentarily after it is deleted.
- 2 If the path is internal, synchronization is enabled, and the route is not in the IGP, do not consider the route.
- 3 Prefer the path with the largest weight (weight is a Cisco proprietary parameter). The weight is generally used to prefer routes which are originated by this router over routes originated by other routers.
- 4 << If the routes have the same weight, prefer the route with the largest local preference.>>

**Note** Locally originated routes are prefered over nonlocally originated routes with a higher local preference.

For example, a route might be originated by the local router using the **network (BGP)** or aggregate-address command, or through redistribution from an IGP. BGP prefers local routes originated by **network (BGP)** and **redistribute** commands over local aggregates originated by the aggregate-address command.

- 5 If the local preference is the same, or if no route was originated by the local router, prefer the route with the shortest autonomous system path. Also note the following:
  - BGP skips this step if the bgp bestpath as-path ignore command is configured.
  - No matter how many autonomous systems are in a set, an autonomous system set counts as
  - The autonomous system confederation sequence is not included in the autonomous system path length.
- 6 If the autonomous system path length is the same, prefer the route with the lowest origin code (IGP < EGP < INCOMPLETE).

7 If the origin codes are the same, prefer the route with the lowest Multi Exit Discriminator (MED) metric attribute.

A comparison is only done if the neighboring autonomous system is the same for all routes considered. Also note the following:

- If the **bgp always-compare-med** command is enabled, BGP compares the MED for routes from neighbors in different autonomous systems. Also, if this command is enabled, it must be enabled throughout the autonomous system; otherwise, routing loops can occur.
- If the **bgp bestpath med-confed** command is enabled, the MED is compared for all routes that are originated within a local confederation.
- BGP will change the MED of a route received from a neighbor with a value of infinity to a value of one less than infinity before the route is inserted into the BGP table.
- The most recent IETF decision regarding BGP MED assigns a value of infinity to a missing MED, making the route lacking the MED variable the least preferred. The default behavior of BGP routers running Cisco IOS software is to treat routes without the MED attribute as having a MED of 0, making the route lacking the MED variable the most preferred. To configure the router to conform to the IETF standard, use the **bgp bestpath missing-as-worst** command.
- If the bgp deterministic med command is enabled, BGP compares the MED variable when choosing among routes advertised by the same sub-autonomous system within a confederation. It the bgp deterministic med command is disabled, the order in which routes are received may affect MED-based best path decisions.
- 8 Prefer the external (EBGP) route over the internal (IBGP) route.
  - All confederation routes are considered internal routes.
- **9** Prefer the route that can be reached through the closest IGP neighbor (the lowest IGP metric).
  - This means the router will prefer the shortest internal path within the autonomous system to reach the destination (the shortest path to the BGP next-hop).
- **10** If the following conditions are all true, insert the route for this path into the IP routing table:
  - Both the best route and this route are external.
  - Both the best route and this route are from the same neighboring autonomous system.
  - The **maximum-paths** command is enabled.

**Note** EBGP load sharing can occur at this point, which means that multiple paths can be installed in the forwarding table.

11 If multipath is enabled, prefer the route that was received first (the oldest route).

This step minimizes route flap in that a newer route will not displace an older route even if the newer route is the preferred route based on the additional criteria discussed below.

If any of the following additional criteria are met, this step is skipped:

- The **bgp bestpath compare-routerid** command is enabled. If this command is enabled, BGP compares similar routes received from external BGP peers and selects the route with the lowest router ID.
- The router ID is the same for multiple routes, for example, the routes were received from the same router.

- No current best path exists, for example, a neighbor advertising the current best path has gone down.
- 12 If multipath is not enabled, prefer the route with the lowest IP address value for the BGP router ID.

The router ID is usually the highest IP address on the router or the loopback (virtual) address, but might be implementation-specific. You can configure a fixed router ID by using the bgp router-id command.

If a route contains route reflector attributes, the originator ID is substituted for the router ID in the route selection process.

13 If multipath is enabled and the originator or router ID is the same for multiple paths, prefer the path with the minimum cluster ID length.

The minimum cluster ID length attribute applies to BGP route reflector environments only.

**14** Prefer the route coming from the lowest neighbor address.

The BGP neighbor configuration uses this IP address. The IP address corresponds to the remote peer used in the TCP connection with the local router.

#### **BGP Multipath Support**

When a BGP speaker learns two identical EBGP paths for a prefix from a neighboring AS, it will choose the path with the lowest route-id as the best path. This best path is installed in the IP routing table. If BGP multipath support is enabled and the EBGP paths are learned from the same neighboring AS, instead of picking one best path, multiple paths are installed in the IP routing table.

During packet switching, depending on the switching mode, either per-packet or per-destination load balancing is performed among the multiple paths. A maximum of six paths is supported. The maximum-paths router configuration command controls the number of paths allowed. By default, BGP will install only one path to the IP routing table.

# **Basic BGP Configuration Tasks**

The BGP configuration tasks are divided into basic and advanced tasks. The first two basic tasks are required to configure BGP; the remaining basic and advanced tasks are optional.

Basic BGP configuration tasks are discussed in the following sections:

- **Enable BGP Routing**
- Configure BGP Neighbors
- Configure BGP Soft Reconfiguration
- **Reset BGP Connections**
- Configure BGP Interactions with IGPs
- Configuring BGP Weights
- Configure BGP Route Filtering by Neighbor
- Configure BGP Path Filtering by Neighbor
- Disable Next-Hop Processing on BGP Updates
- Configure the BGP Version
- Set the Network Weight

- Configure the Multi Exit Discriminator Metric
- Monitor and Maintain BGP

# **Advanced BGP Configuration Tasks**

Advanced, optional BGP configuration tasks are discussed in the following sections:

- Use Route Maps to Modify Updates
- Reset EBGP Connections Immediately upon Link Failure
- Configure Aggregate Addresses
- Disable Automatic Summarization of Network Numbers
- Configure BGP Community Filtering
- Configuring BGP Conditional Advertisement
- Configure a Routing Domain Confederation
- Configure a Route Reflector
- Configure BGP Peer Groups
- Indicate Backdoor Routes
- Modify Parameters While Updating the IP Routing Table
- Set Administrative Distance
- Adjust BGP Timers
- Change the Local Preference Value
- Redistribute Network 0.0.0.0
- Select Path Based on MEDs from Other Autonomous Systems
- Configure the Router to Use the MED to Choose a Path from Sub-AS Paths
- Configure Route Dampening

For information on configuring features that apply to multiple IP routing protocols (such as redistributing routing information), see the chapter "Configuring IP Routing Protocol-Independent Features."

# **Configure Basic BGP Features**

The tasks in this section are for configuring basic BGP features.

# **Enable BGP Routing**

To enable BGP routing, establish a BGP routing process by using the following commands beginning in global configuration mode:

Step	Command	Purpose
1	router bgp autonomous-system	Enable a BGP routing process, which places you in router configuration mode.

Step	Command	Purpose
2	network network-number [mask network-mask] [route-map route-map-name]	Flag a network as local to this autonomous system and enter it to the BGP table.

**Note** For exterior protocols, a reference to an IP network from the **network** router configuration command controls only which networks are advertised. This is in contrast to Interior Gateway Protocols (IGP), such as IGRP, which also use the **network** command to determine where to send updates.

**Note** The **network** command is used to inject IGP routes into the BGP table. The *network-mask* portion of the command allows supernetting and subnetting. The router's resources, such as configured NVRAM or RAM, determine the number of **network** commands you can use. Alternatively, you could use the **redistribute** command to achieve the same result.

### Configure BGP Neighbors

Like other Exterior Gateway Protocols (EGPs), BGP must completely understand the relationships it has with its neighbors. Therefore, this task is required.

BGP supports two kinds of neighbors: internal and external. *Internal neighbors* are in the same autonomous system; external neighbors are in different autonomous systems. Normally, external neighbors are adjacent to each other and share a subnet, while internal neighbors may be anywhere in the same autonomous system.

To configure BGP neighbors, use the following command in router configuration mode:

Command	Purpose
neighbor {ip-address   peer-group-name} remote-as number	Specify a BGP neighbor.

See the "BGP Neighbor Configuration Examples" section at the end of this chapter for an example of configuring BGP neighbors.

### Configure BGP Soft Reconfiguration

Whenever there is a change in the policy, the BGP session has to be cleared for the new policy to take effect. Clearing a BGP session causes cache invalidation and results in a tremendous impact on the operation of networks.

Soft reconfiguration allows policies to be configured and activated without clearing the BGP session. Soft reconfiguration is recommended; it is done on a per-neighbor basis.

- When soft reconfiguration is used to generate inbound updates from a neighbor, it is called inbound soft reconfiguration.
- When soft reconfiguration is used to send a new set of updates to a neighbor, it is called outbound soft reconfiguration.

Performing inbound reconfiguration enables the new inbound policy to take effect. Performing outbound reconfiguration causes the new local outbound policy take effect without resetting the BGP session. As a new set of updates is sent during outbound policy reconfiguration, a new inbound policy of the neighbor can also take effect.

In order to generate new inbound updates without resetting the BGP session, the local BGP speaker should store all the received updates without modification, regardless of whether it is accepted or denied by the current inbound policy. This is memory intensive and should be avoided. On the other hand, outbound soft reconfiguration does not have any memory overhead. One could trigger an outbound reconfiguration in the other side of the BGP session to make the new inbound policy take effect.

To allow inbound reconfiguration, BGP should be configured to store all received updates. Outbound reconfiguration does not require preconfiguration.

You can configure the Cisco IOS software to start storing received updates, which is required for inbound BGP soft reconfiguration. Outbound reconfiguration does not require inbound soft reconfiguration to be enabled.

To configure BGP soft configuration, use the following command in router configuration mode:

Command	Purpose
neighbor {ip-address   peer-group-name}	Configure BGP soft reconfiguration.
soft-reconfiguration [inbound]	This command requires at least one keyword.
	<b>Note</b> The <b>neighbor soft-reconfiguration</b> command requires at least one keyword. Currently the only keyword available is <b>inbound</b> , so the use of <b>inbound</b> is not optional.

Our implementation of BGP supports BGP Versions 2, 3, and 4. If the neighbor does not accept default Version 4, dynamic version negotiation is implemented to negotiate down to Version 2.

If you specify a BGP peer group by using the *peer-group-name* argument, all members of the peer group will inherit the characteristic configured with this command.

### **Reset BGP Connections**

Once you have defined two routers to be BGP neighbors, they will form a BGP connection and exchange routing information. If you subsequently change a BGP filter, weight, distance, version, or timer, or make a similar configuration change, you must reset BGP connections for the configuration change to take effect. Use either of the following commands in EXEC mode to reset BGP connections:

Command	Purpose
clear ip bgp address	Reset a particular BGP connection.
clear ip bgp *	Reset all BGP connections.

# Configure BGP Interactions with IGPs

If your autonomous system will be passing traffic through it from another autonomous system to a third autonomous system, it is very important that your autonomous system be consistent about the routes that it advertises. For example, if your BGP were to advertise a route before all routers in your network had learned about the route through your IGP, your autonomous system could receive traffic

that some routers cannot yet route. To prevent this from happening, BGP must wait until the IGP has propagated routing information across your autonomous system. This causes BGP to be synchronized with the IGP. Synchronization is enabled by default.

In some cases, you do not need synchronization. If you will not be passing traffic from a different autonomous system through your autonomous system, or if all routers in your autonomous system will be running BGP, you can disable synchronization. Disabling this feature can allow you to carry fewer routes in your IGP and allow BGP to converge more quickly. To disable synchronization, use the following command in router configuration mode:

Command	Purpose
no synchronization	Disable synchronization between BGP and an IGP.

When you disable synchronization, you should also clear BGP sessions using the clear ip bgp command.

See the "BGP Path Filtering by Neighbor Example" section at the end of this chapter for an example of BGP synchronization.

In general, you will not want to redistribute most BGP routes into your IGP. A common design is to redistribute one or two routes and to make them exterior routes in IGRP, or have your BGP speaker generate a default route for your autonomous system. When redistributing from BGP into IGP, only the routes learned using EBGP get redistributed.

In most circumstances, you also will not want to redistribute your IGP into BGP. Just list the networks in your autonomous system with **network** router configuration commands and your networks will be advertised. Networks that are listed this way are referred to as local networks and have a BGP origin attribute of "IGP." They must appear in the main IP routing table and can have any source; for example, they can be directly connected or learned via an IGP. The BGP routing process periodically scans the main IP routing table to detect the presence or absence of local networks, updating the BGP routing table as appropriate.

If you do perform redistribution into BGP, you must be very careful about the routes that can be in your IGP, especially if the routes were redistributed from BGP into the IGP elsewhere. This creates a situation where BGP is potentially injecting information into the IGP and then sending such information back into BGP, and vice versa.

Networks that are redistributed into BGP from the EGP protocol will be given the BGP origin attribute "EGP." Other networks that are redistributed into BGP will have the BGP origin attribute of "incomplete." The origin attribute in our implementation is only used in the path selection process.

### Configuring BGP Weights

A weight is a number that you can assign to a path so that you can control the path selection process. The administrative weight is local to the router. A weight can be a number from 0 to 65535. Any path that a Cisco router originates will have a default weight of 32768; other paths have weight 0. If you have particular neighbors that you want to prefer for most of your traffic, you can assign a higher weight to all routes learned from that neighbor.

Weights can be assigned based on autonomous system path access lists. A given weight becomes the weight of the route if the autonomous system path is accepted by the access list. Any number of weight filters are allowed. Weights can also be assigned via route maps.

### Disable AS Path Comparison

RFC 1771, the IETF document defining BGP, does not include as-path as part of the "tie-breaker" decision algorithm. By default, Cisco IOS software considers the as-path as a part of the decision algorithm. This enhancement makes it possible to modify the decision algorithm, bringing the router's behavior in selecting a path more in line with the IETF specification.

To prevent the router from considering the as-path length when selecting a route, use the following command in router configuration mode:

Command	Purpose
bgp bestpath as-path ignore	Configures the router to ignore as-path length in selecting a route.

### Configure BGP Route Filtering by Neighbor

You can filter BGP advertisements in two ways:

- Use AS-path filters, as with the ip as-path access-list global configuration command and the neighbor filter-list command
- Use access or prefix lists, as with the **neighbor distribute-list** command.

Filtering using prefix lists is described in "Configuring BGP Filtering Using Prefix Lists".

If you want to restrict the routing information that the Cisco IOS software learns or advertises, you can filter BGP routing updates to and from particular neighbors. To do this, you can either define an access list or a prefix list and apply it to the updates.

**Note** Distribute-list filters are applied to network numbers and not autonomous system paths.

To filter BGP routing updates, use the following command in router configuration mode:

Command	Purpose
neighbor {ip-address   peer-group-name} distribute-list {access-list-number   name} {in   out}	Filter BGP routing updates to/from neighbors as specified in an access list.
	Note The neighbor prefix-list command can be used as an alternative to the neighbor distribute-list command, but you cannot use both commands in configuring the same BGP peer.

**Note** Although **neighbor prefix-list** can be used as an alternative to the neighbor **distribute-list** command, do not use attempt to apply both **neighbor prefix list** and **neighbor distribute-list** filtering to the same neighbor.

# Configuring BGP Filtering Using Prefix Lists

Prefix lists can be used as an alternative to access lists in many BGP route filtering commands. "How the System Filters Traffic by Prefix List" describes the way prefix list filtering works.

The advantages of using prefix lists are:

- Significant performance improvement in loading and route lookup of large lists
- Support for incremental updates

Filtering using extended access lists does not support incremental updates.

• More user-friendly command-line interface

The command-line interface for using access lists to filter BGP updates is difficult to understand and use, since it uses the packet filtering format.

Greater flexibility

Before using a prefix list in a command, you must set up a prefix list, and you may want to assign sequence numbers to the entries in the prefix list.

### How the System Filters Traffic by Prefix List

Filtering by prefix list involves matching the prefixes of routes with those listed in the prefix list. When there is a match, the route is used. The matching is similar to that of the access list. More specifically, whether a prefix is permitted or denied is based upon the following rules:

- An empty prefix list permits all prefixes.
- An implicit deny is assumed if a given prefix does not match any entries of a prefix list.
- When multiple entries of a prefix list match a given prefix, the sequence number of a prefix list entry identifies the entry with the lowest sequence number. In this case, the entry with the smallest sequence number is considered to be the "real" match.

The router begins the search at the top of the prefix list, with the sequence number 1. Once a match or deny occurs, the router does not need to go through the rest of the prefix list. For efficiency, you may want to put the most common matches or denies near the top of the list, using the argument seq in the **ip prefix-list** command. The **show** commands always include the sequence numbers in their output.

Sequence numbers are generated automatically unless you disable this automatic generation. If you disable the automatic generation of sequence numbers, you must specify the sequence number for each entry using the *seq-value* argument of the **ip prefix-list** command.

Regardless of whether the default sequence numbers are used in configuring a prefix list, a sequence number does not need to be specified when removing a configuration entry.

**Show** commands include the sequence numbers in their output.

#### Create a Prefix List

To create a prefix list, use the following command in router configuration mode:

Command	Purpose
ip prefix-list list-name [seq seq-value] deny permit network/len [ge ge-value] [le le-value]	Creates a prefix list with the name specified for <i>list-name</i> .

**Note** To create a prefix list you must enter at least one **permit** or **deny** clause.

To remove a prefix list and all of its entries, use the following command in router configuration mode:

Command	Purpose
no ip prefix-list list-name [seq seq-value] deny permit network/len [ge ge-value] [le le-value]	Removes a prefix list with the name specified for <i>list-name</i> .

### Configure a Prefix List Entry

You can add entries to a prefix list individually. To configure an entry in a prefix list, use the following command in router configuration mode:

Command	Purpose
ip prefix-list list-name seq seq-value deny permit network/len [ge ge-value] [le le-value]	Creates an entry in a prefix list and assigns a sequence number to the entry.

The optional keywords **ge** and **le** can be used to specify the range of the prefix length to be matched for prefixes that are more specific than *network/len*. An exact match is assumed when neither **ge** nor **le** is specified. The range is assumed to be from *ge-value* to 32 if only the **ge** attribute is specified, and from **len** to *le-value* if only the **le** attribute is specified.

A specified *ge-value* and/or *le-value* must satisfy the following condition:

```
len < ge-value <= le-value <= 32
```

For example, to deny all prefixes matching /24 in 128.0.0.0/8, you would use:

```
ip prefix-list abc deny 128.0.0.0/8 ge 24 le 24
```

**Note** You can specify sequence values for prefix list entries in any increments you want (the automatically generated numbers are incremented in units of 5). If you specify the sequence values in increments of 1, you cannot insert additional entries into the prefix list. If you choose very large increments, you could run out of sequence values.

#### Configure How Sequence Numbers of Prefix List Entries Are Specified

By default, the sequence numbers are automatically generated when you create a prefix list entry. Sequence numbers can be suppressed with the command **no ip prefix-list sequence-number**. Sequence values are generated in increments of 5. The first sequence value generated in a prefix list would be 5, then 10, then 15, and so on. If you specify a value for an entry and then do not specify values for subsequent entries, the assigned (generated) sequence values are incremented in units of five. For example, if you specify that the first entry in the prefix list have a sequence value of 3, and then do not specify sequence values for the other entries, the automatically generated numbers will be 8, 13, 18, and so on.

To disable the automatic generation of sequence numbers, use the following command:

Command	Purpose
no ip prefix-list sequence-number	Disables the automatic generation of the sequence numbers for prefix list entries.

To re-enable automatic generation of the sequence numbers of prefix list entries, use the following command in router configuration mode:

Command	Purpose
ip prefix-list sequence-number	Enables the automatic generation of the sequence numbers of prefix list entries. The default is enable.

If you disable automatic generation of sequence numbers in a prefix list, you must specify the sequence number for each entry using the seq-value argument of the ip **prefix-list** command.

Regardless of whether the default sequence numbers are used in configuring a prefix list, a sequence number does not need to be specified when de-configuring an entry. Show commands include the sequence numbers in their output.

#### Delete a Prefix List or Prefix List Entries

To delete a prefix list, use the following command in router configuration mode:

You can delete entries from a prefix list individually. To delete an entry in a prefix list, use the following command in router configuration mode:

Command	Purpose
no ip prefix-list seq seq-value	Delete an entry in a prefix list.

**Note** The sequence number of an entry does not need to be specified when you delete the entry.

#### Show Prefix Entries

To display information about prefix tables, prefix table entries, the policy associated with a node, or specific information about an entry, use the following commands:

show ip prefix-list [detail summary]	Display information about all prefix lists.
show ip prefix-list [detail summary] name	Display a table showing the entries in a prefix list.
show ip prefix-list name [network/len]	Display the policy associated with the node.
show ip prefix-list name [seq seq-num]	Display the prefix list entry with a given sequence number.
show ip prefix-list name [network/len] longer	Display all entries of a prefix list that are more specific than the given network and length.
show ip prefix-list name [network/len] first-match	Display the entry of a prefix list that matches the given prefix (network and length of prefix).

#### Clear the Prefix Table Hit Count

To clear the hit count of prefix list entries, use the following command in EXEC mode:

clear ip prefix-list name [network/len]	Enables the automatic generation of the sequence
	numbers of prefix list entries. The default is enable.

# Configure BGP Path Filtering by Neighbor

In addition to filtering routing updates based on network numbers, you can specify an access list filter on both incoming and outbound updates based on the BGP autonomous system paths. Each filter is an access list based on regular expressions. To do this, define an autonomous system path access list and apply it to updates to and from particular neighbors. See the "Regular Expressions" appendix in the *Dial Solutions Command Reference* for more information on forming regular expressions.

To configure BGP path filtering, use the following commands beginning in global configuration mode:

Step	Command	Purpose
1	<pre>ip as-path access-list access-list-number {permit   deny} as-regular-expression</pre>	Define a BGP-related access list.
2	router bgp autonomous-system	Enter router configuration mode.
3	<b>neighbor</b> {ip-address   peer-group-name} <b>filter-list</b> access-list-number { <b>in</b>   <b>out</b>   <b>weight</b> weight}	Establish a BGP filter.

See the "BGP Path Filtering by Neighbor Example" section at the end of this chapter for an example of BGP path filtering by neighbor.

# Disable Next-Hop Processing on BGP Updates

You can configure the Cisco IOS software to disable next-hop processing for BGP updates to a neighbor. This might be useful in nonmeshed networks such as Frame Relay or X.25, where BGP neighbors might not have direct access to all other neighbors on the same IP subnet. There are two ways to disable next-hop processing:

- provide a specific address to be used instead of the next-hop address (manually configuring each address)
- use a route map to specify that the address of the remote peer for matching inbound routes, or the local router for matching outbound routes (automatic method)

#### Disable Next-Hop Processing Using a Specific Address

To disable next-hop processing and provide a specific address to be used instead of the next-hop address, use the following command in router configuration mode:

Command	Purpose
neighbor {ip-address   peer-group-name} next-hop-self	Disable next-hop processing on BGP updates to a neighbor.

Configuring this command causes the current router to advertise itself as the next hop for the specified neighbor. Therefore, other BGP neighbors will forward to it packets for that address. This is useful in a nonmeshed environment, since you know that a path exists from the present router to that address. In a fully meshed environment, this is not useful, since it will result in unnecessary extra hops and because there might be a direct access through the fully meshed cloud with fewer hops.

### Disable Next-Hop Processing Using a Route Map

To override the inbound next hop setting for BGP routes and specify that the next hop of the matching routes is to be the IP address of the remote peer, or to set the peering address of the local router to be the next hop of the matching routes, use the neighbor next-hop-self command.

This approach is less cumbersome that configuring a specific address to be the next hop for BGP routes, especially at major interconnects, since each

To configure the neighbor peering address to be used for the next hop address, use the following route map configuration command:

Command	Purpose
set ip next-hop ip-address [ip-address] [peer-address]	In an inbound route map of a BGP peer, sets the next hop of the matching routes to be the neighbor peering address, overriding any third-party next hops and allowing the same route map to be applied to multiple BGP peers to override third-party next hops.
	With an outbound route map of a BGP peer, sets the next hop of the received address to the peering address of the local router, disabling the next hop calculation.

# Configure the BGP Version

By default, BGP sessions begin using BGP Version 4 and negotiating downward to earlier versions if necessary. To prevent negotiation and force the BGP version used to communicate with a neighbor, use the following command in router configuration mode:

Command	Purpose
neighbor {ip-address   peer-group-name} version value	Specify the BGP version to use when communicating with a neighbor.

### Configure the Multi Exit Discriminator Metric

BGP uses the Multi Exit Discriminator (MED) metric as a hint to external neighbors about preferred paths. (The name of this metric for BGP Versions 2 and 3 is INTER\_AS\_METRIC.) You can set the MED of the redistributed routes by performing the following task. All the routes without a MED will also be set to this value. Use the following command in router configuration mode:

Command	Purpose
default-metric number	Set a multi exit discriminator.

Alternatively, you can set the MED using the route-map command. See the "BGP Route Map Examples" section at the end of this chapter for examples of using BGP route maps.

# **Configure Advanced BGP Features**

The tasks in this section are for configuring advanced BGP features.

### Use Route Maps to Modify Updates

You can use a route map on a per-neighbor basis to filter updates and modify various attributes. A route map can be applied to either inbound or outbound updates. Only the routes that pass the route map are sent or accepted in updates.

On both the inbound and the outbound updates, we support matching based on autonomous system path, community, and network numbers. Autonomous system path matching requires the **as-path access-list** command, community based matching requires the **community-list** command and network-based matching requires the **ip access-list** command. Use the following command in router configuration mode:

Command	Purpose
neighbor {ip-address   peer-group-name} route-map route-map-name {in   out}	Apply a route map to incoming or outgoing routes.

See the "BGP Route Map Examples" section at the end of this chapter for BGP route-map examples.

### Reset EBGP Connections Immediately upon Link Failure

Normally, when a link between external neighbors goes down, the BGP session will not be reset immediately. If you want the EBGP session to be reset as soon as an interface goes down, use the following command in router configuration mode:

Command	Purpose
bgp fast-external-fallover	Automatically reset EBGP sessions.

# Configure Aggregate Addresses

Classless interdomain routing (CIDR) enables you to create aggregate routes (or *supernets*) to minimize the size of routing tables. You can configure aggregate routes in BGP either by redistributing an aggregate route into BGP or by using the conditional aggregation feature described in the following task table. An aggregate address will be added to the BGP table if there is at least one more specific entry in the BGP table.

To create an aggregate address in the routing table, use one or more of the following commands in router configuration mode:

Command	Purpose
aggregate-address address mask	Create an aggregate entry in the BGP routing table.
aggregate-address address mask as-set	Generates autonomous system set path information.
aggregate-address address-mask summary-only	Advertise summary addresses only.
aggregate-address address mask suppress-map map-name	Suppress selected, more specific routes.
aggregate-address address mask advertise-map map-name	Generate an aggregate based on conditions specified by the route map.
aggregate-address address mask attribute-map map-name	Generate an aggregate with attributes specified in the route map.

See the "BGP Aggregate Route Examples" section at the end of this chapter for examples of using BGP aggregate routes.

### Disable Automatic Summarization of Network Numbers

In BGP Version 3, when a subnet is redistributed from an IGP into BGP, only the network route is injected into the BGP table. By default, this automatic summarization is enabled. To disable automatic network number summarization, use the following command in router configuration mode:

Command	Purpose
no auto-summary	Disable automatic network summarization.

# Configure BGP Community Filtering

BGP supports transit policies via controlled distribution of routing information. The distribution of routing information is based on one of the following three values:

- IP address (see the "Configure BGP Route Filtering by Neighbor" section earlier in this chapter).
- The value of the AS PATH attribute (see the "Configure BGP Path Filtering by Neighbor" section earlier in this chapter).
- The value of the COMMUNITIES attribute (as described in this section).

The COMMUNITIES attribute is a way to group destinations into communities and apply routing decisions based on the communities. This method simplifies a BGP speaker's configuration that controls distribution of routing information.

A community is a group of destinations that share some common attribute. Each destination can belong to multiple communities. Autonomous system administrators can define to which communities a destination belongs. By default, all destinations belong to the general Internet community. The community is carried as the COMMUNITIES attribute.

The COMMUNITIES attribute is an optional, transitive, global attribute in the numerical range from 1 to 4,294,967,200. Along with Internet community, there are a few predefined, well-known communities, as follows:

- internet—Advertise this route to the Internet community. All routers belong to it.
- **no-export**—Do not advertise this route to EBGP peers.
- **no-advertise**—Do not advertise this route to any peer (internal or external).
- local-as—Send this route to peers in other sub-autonomous systems within the local confederation. Do not advertise this route to an external system.

Based on the community, you can control which routing information to accept, prefer, or distribute to other neighbors. A BGP speaker can set, append, or modify the community of a route when you learn, advertise, or redistribute routes. When routes are aggregated, the resulting aggregate has a COMMUNITIES attribute that contains all communities from all the initial routes.

You can use community lists to create groups of communities to use in a match clause of a route map. Just like an access list, a series of community lists can be created. Statements are checked until a match is found. As soon as one statement is satisfied, the test is concluded.

To create a community list, use the following command in global configuration mode:

Command	Purpose	
ip community-list community-list-number {permit	Create a community list.	
<b>deny</b> } community-number		

To set the COMMUNITIES attribute and match clauses based on communities, see the **match community-list** and **set community** commands in the "Redistribute Routing Information" section in the "Configuring IP Routing Protocol-Independent Features" chapter.

By default, no COMMUNITIES attribute is sent to a neighbor. You can specify that the COMMUNITIES attribute be sent to the neighbor at an IP address by using the following command in router configuration mode:

Command	Purpose
neighbor {ip-address   peer-group-name}	Specify that the COMMUNITIES attribute be sent to
send-community	the neighbor at this IP address.

To remove communities from the community attribute of an inbound or outbound update using a route map to filter and determine the communities to be deleted, use the following command in router configuration mode:

Command	Purpose
set comm-list list-num delete	Removes communities in a community attribute that
	match a standard or extended community list.

**Note** To delete a BGP community using this feature, each entry of a standard community list should list only one community.

#### Specify the Format for the Community

A BGP community is displayed in a two-part format two bytes long in the **show ip bgp community** command output, as well as wherever communities are displayed in the router configuration, such as router maps and community lists. In the most recent version of the RFC for BGP, a community is of the form AA:NN, where the first part is the AS number and the second part is a 2 byte number. The Cisco default community format is in the format NNAA.

To display BGP communities in the new format, use the following command in global configuration mode:

Command	Purpose
ip bgp-community new-format	Displays and parses BGP BGP communities in the format AA:NN.

# Configuring BGP Conditional Advertisement

The BGP advertises routes from its routing table to external peers (peers in different autonomous systems) by default. The BGP Conditional Advertisement feature provides additional control of route advertisement depending on the existence of other prefixes in the BGP table. Normally, routes are propagated regardless of the existence of a different path. The BGP Conditional Advertisement feature uses the non-exist-map and the advertise-map to track routes by the route prefix. If a route

prefix is not present in the non-exist-map, the route specified by the advertise-map is announced. The announced route is installed to the BGP routing table as a locally originated route and will behave as a locally originated route. The announced route will be originated by BGP only if the corresponding IGP route exists. After the prefix is locally originated by BGP, BGP will advertise the prefix to internal and external peers. If the route prefix is present, the route in the advertise-map is not announced.

This feature can be useful in a multihomed network, in which some prefixes are to be advertised to one of the providers, only if information from the other provider is missing. This condition would indicate a failure in the peering session, or partial reachability.

**Note** The conditional BGP announcements are sent in addition to the normal announcements that a BGP router sends to its peers.

#### The Size of the Global BGP Table Is Reduced

If the same information is advertised to all providers in a multihomed environment, the information is duplicated in the global BGP table. When the BGP Conditional Advertisement feature is used, only partial routes are advertised to each provider, and the size of the global BGP table is not increased with redundant information.

#### Better Inbound Traffic Control

The user can guarantee the path that inbound traffic will follow because only specific paths are advertised to providers.

**Note** Autonomous system path list information cannot be used for conditional advertisement because the IP routing table does not contain autonomous system path information.

# **BGP Conditional Advertisement Configuration Task List**

See the following section for configuration tasks for the BGP Conditional Advertisement feature. Each task in the list indicates if the task is optional or required.

- Configure the route-maps that will be used in conjunction with the advertise-map and the non-exist-map. This step may include the configuration of access-lists and prefix-lists. (Required)
- Configure the router to run BGP. (Required)
- Configure the advertise-map and the non-exist-map with the neighbor advertise-map **non-exist-map** router configuration command. (Required)
- Verify that the BGP Condition Advertisement feature has been configured with the **show ip bgp** neighbor command. (Optional)

#### Conditional Advertisement of a Set of Routes

To conditionally advertise a set of routes, use the following commands begining in router configuration mode:

	Command	Purpose
Step 1	router bgp as-number	Configures the router to run a BGP process.
Step 2	neighbor ip-address remote-as as-number	Specifies the peer that should receive conditional advertisement for a given set routes.
Step 3	neighbor ip-address advertise-map map1 non-exist-map map2	Configures the advertise-map and non-exist map for the BGP Conditional Advertisement feature.

See the "BGP Conditional Advertisement Configuration Examples" section at the end of this chapter for an example configuration of BGP conditional advertisement.

### Verifying BGP Conditional Advertisement feature

To verify that the BGP Condition Advertisement feature has been configured, use the **show ip bgp neighbor** command. The **show ip bgp neighbor EXEC** command will show the status of the BGP Conditional Advertisement feature as initialized or uninitialized.

The following example shows output from the **show ip bgp neighbor EXEC** command:

```
router# show ip bgp neigbor 172.17.1.1
BGP neighbor is 172.17.1.1, remote AS 65200, internal link
 Description: link to boston as 65200
  BGP version 4, remote router ID 31.1.1.1
 BGP state = Established, up for 01:04:30
 Last read 00:00:30, hold time is 180, keepalive interval is 60 seconds
  Neighbor capabilities:
   Route refresh:advertised and received
   Address family IPv4 Unicast:advertised and received
  Received 83 messages, 0 notifications, 0 in queue
  Sent 78 messages, 0 notifications, 0 in queue
  Route refresh request:received 0, sent 0
  Minimum time between advertisement runs is 5 seconds
 For address family: IPv4 Unicast
 BGP table version 18, neighbor version 18
  Index 2, Offset 0, Mask 0x4
  Inbound soft reconfiguration allowed
  {\tt NEXT\_HOP} is always this router
  Community attribute sent to this neighbor
  Condition-map old-route, Advertise-map new-route, status: Uninitialized
  2 accepted prefixes consume 72 bytes
  Prefix advertised 7, suppressed 0, withdrawn 4
  Connections established 1; dropped 0
  Last reset 01:05:29, due to Soft reconfig change
```

### **BGP Conditional Advertisement Troubleshooting Tips**

This section provides troubleshooting information for the BGP conditional advertisement feature.

The BGP Conditional Advertisement feature is based on the nonexistence of a prefix and the advertisement of another. Normally, only two problems can occur:

- The tracked prefix exists, but the conditional advertisement occurs.
- The tracked prefix does not exist, and the conditional advertisement does not occur.

The same method of troubleshooting is used for both problems:

- Verify the existence (or not) of the tracked prefix in the BGP table with the show ip bgp EXEC command.
- Verify the advertisement (or not) of the other prefix using the show ip bgp neighbor advertised-routes EXEC command.

The user needs to ensure that all of the characteristics specified in the route maps match the routes in the BGP table.

### Configure a Routing Domain Confederation

One way to reduce the IBGP mesh is to divide an autonomous system into multiple autonomous systems and group them into a single confederation. To the outside world, the confederation looks like a single autonomous system. Each autonomous system is fully meshed within itself, and has a few connections to other autonomous systems in the same confederation. Even though the peers in different autonomous systems have EBGP sessions, they exchange routing information as if they were IBGP peers. Specifically, the next-hop, MED, and local preference information is preserved. This enables to us to retain a single Interior Gateway Protocol (IGP) for all of the autonomous systems.

To configure a BGP confederation, you must specify a confederation identifier. To the outside world, the group of autonomous systems will look like a single autonomous system with the confederation identifier as the autonomous system number. To configure a BGP confederation identifier, use the following command in router configuration mode:

Command	Purpose
bgp confederation identifier autonomous-system	Configure a BGP confederation.

In order to treat the neighbors from other autonomous systems within the confederation as special EBGP peers, use the following command in router configuration mode:

Command	Purpose
bgp confederation peers autonomous-system [autonomous-system]	Specify the autonomous systems that belong to the confederation.

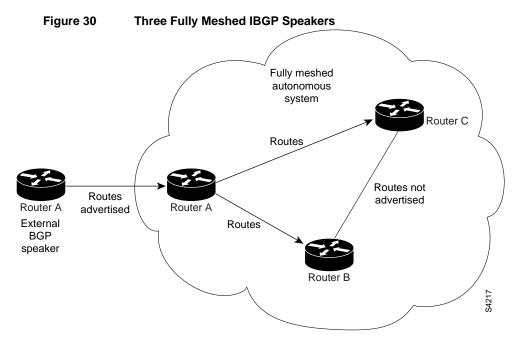

See the "BGP Conditional Advertisement Configuration Examples" section at the end of this chapter for an example configuration of several peers in a confederation.

For an alternative way to reduce the IBGP mesh, see the next section, "Configure a Route Reflector."

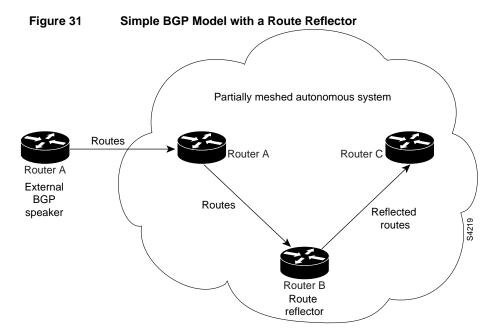

# Configure a Route Reflector

BGP requires that all of the IBGP speakers be fully meshed. However, this requirement does not scale when there are many IBGP speakers. Instead of configuring a confederation, another way to reduce the IBGP mesh is to configure a route reflector.

Figure 30 illustrates a simple IBGP configuration with three IBGP speakers (Routers A, B, and C). Without route reflectors, when Router A receives a route from an external neighbor, it must advertise it to both Routers B and C. Routers B and C do not readvertise the IBGP learned route to other IBGP speakers because the routers do not pass routes learned from internal neighbors on to other internal neighbors, thus preventing a routing information loop.

With route reflectors, all IBGP speakers need not be fully meshed because there is a method to pass learned routes to neighbors. In this model, an internal BGP peer is configured to be a route reflector responsible for passing IBGP learned routes to a set of IBGP neighbors. In Figure 31, Router B is configured as a route reflector. When the route reflector receives routes advertised from Router A, it advertises them to Router C, and vice versa. This scheme eliminates the need for the IBGP session between Routers A and C.

The internal peers of the route reflector are divided into two groups: client peers and all the other routers in the autonomous system (nonclient peers). A route reflector reflects routes between these two groups. The route reflector and its client peers form a cluster. The nonclient peers must be fully meshed with each other, but the client peers need not be fully meshed. The clients in the cluster do not communicate with IBGP speakers outside their cluster.

Figure 32 illustrates a more complex route reflector scheme. Router A is the route reflector in a cluster with Routers B, C, and D. Routers E, F, and G are fully meshed, nonclient routers.

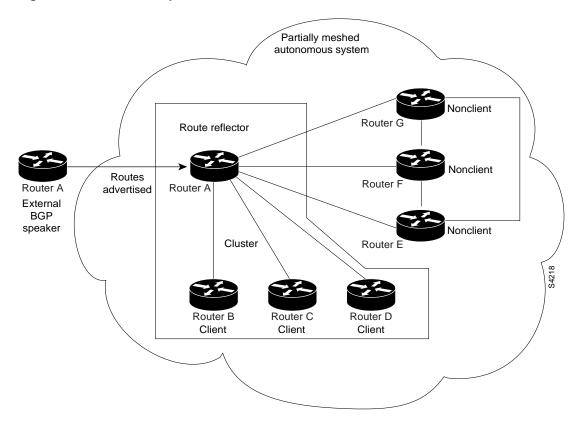

Figure 32 More Complex BGP Route Reflector Model

When the route reflector receives an advertised route, depending on the neighbor, it does the following:

- A route from an external BGP speaker is advertised to all clients and nonclient peers.
- A route from a nonclient peer is advertised to all clients.
- A route from a client is advertised to all clients and nonclient peers. Hence, the clients need not be fully meshed.

To configure a route reflector and its clients, use the following command in router configuration mode:

Command	Purpose
neighbor ip-address route-reflector-client	Configure the local router as a BGP route reflector and the specified neighbor as a client.

Along with route reflector-aware BGP speakers, it is possible to have BGP speakers that do not understand the concept of route reflectors. They can be members of either client or nonclient groups. This allows easy, gradual migration from the old BGP model to the route reflector model. Initially, you could create a single cluster with a route reflector and a few clients. All the other IBGP speakers could be nonclient peers to the route reflector and then more clusters could be created gradually.

An autonomous system can have multiple route reflectors. A route reflector treats other route reflectors just like other IBGP speakers. A route reflector can be configured to have other route reflectors in a client group or nonclient group. In a simple configuration, the backbone could be

divided into many clusters. Each route reflector would be configured with other route reflectors as nonclient peers (thus, all the route reflectors will be fully meshed). The clients are configured to maintain IBGP sessions with only the route reflector in their cluster.

Usually a cluster of clients will have a single route reflector. In that case, the cluster is identified by the router ID of the route reflector. To increase redundancy and avoid a single point of failure, a cluster might have more than one route reflector. In this case, all route reflectors in the cluster must be configured with the 4-byte cluster ID so that a route reflector can recognize updates from route reflectors in the same cluster. All the route reflectors serving a cluster should be fully meshed and all of them should have identical sets of client and nonclient peers.

If the cluster has more than one route reflector, configure the cluster ID by using the following command in router configuration mode:

Command	Purpose
bgp cluster-id cluster-id	Configure the cluster ID.

Use the **show ip bgp** command to display the originator ID and the cluster-list attributes.

By default, the clients of a route reflector are not required to be fully meshed and the routes from a client are reflected to other clients. However, if the clients are fully meshed, the route reflector does not need to reflect routes to clients. To disable client-to-client route reflection, use the following command in router configuration mode:

Command	Purpose
no bgp client-to-client reflection	Disable client-to-client route reflection.

Note If client-to-client reflection is enabled, the clients of a route reflector cannot be members of a peer group.

As the IBGP learned routes are reflected, it is possible for routing information to loop. The route reflector model has the following mechanisms to avoid routing loops:

- Originator-ID is an optional, nontransitive BGP attribute. This is a 4-byte attributed created by a route reflector. The attribute carries the router ID of the originator of the route in the local autonomous system. Therefore, if a misconfiguration causes routing information to come back to the originator, the information is ignored.
- Cluster-list is an optional, nontransitive BGP attribute. It is a sequence of cluster IDs that the route has passed. When a route reflector reflects a route from its clients to nonclient peers, it appends the local cluster ID to the cluster-list. If the cluster-list is empty, it creates a new one. Using this attribute, a route reflector can identify if routing information is looped back to the same cluster due to misconfiguration. If the local cluster ID is found in the cluster-list, the advertisement is ignored.
- Using set clauses in outbound route maps modifies attributes, possibly creating routing loops. To avoid this, set clauses of outbound route maps are ignored for routes reflected to IBGP peers.

# Configure BGP Peer Groups

Often, in a BGP speaker, many neighbors are configured with the same update policies (that is, the same outbound route maps, distribute lists, filter lists, update source, and so on). Neighbors with the same update policies can be grouped into peer groups to simplify configuration and, more importantly, to make updating more efficient. When you have many peers, this approach is highly recommended.

The three steps to configure a BGP peer group, described in the following sections, are as follows:

- 1 Create the Peer Group
- 2 Assign Options to the Peer Group
- 3 Make Neighbors Members of the Peer Group

You can disable a BGP peer or peer group without removing all the configuration information using the **neighbor shutdown** command.

#### Create the Peer Group

To create a BGP peer group, use the following command in router configuration mode:

Command	Purpose
neighbor peer-group-name peer-group	Create a BGP peer group.

### Assign Options to the Peer Group

After you create a peer group, you configure the peer group with **neighbor** commands. By default, members of the peer group inherit all the configuration options of the peer group. Members can also be configured to override the options that do not affect outbound updates.

Peer group members will always inherit the following: remote-as (if configured), version, update-source, out-route-map, out-filter-list, out-dist-list, minimum-advertisement-interval, and next-hop-self. All the peer group members will inherit changes made to the peer group.

To assign configuration options to an individual neighbor, specify any of the following commands using the IP address. To assign the options to a peer group, specify any of the commands using the peer group name. Use any of these commands in router configuration mode.

Command	Purpose
neighbor {ip-address   peer-group-name} remote-as number	Specify a BGP neighbor.
neighbor {ip-address   peer-group-name} description text	Associate a description with a neighbor.
neighbor {ip-address   peer-group-name} default-originate [route-map map-name]	Allow a BGP speaker (the local router) to send the default route 0.0.0.0 to a neighbor for use as a default route.
neighbor {ip-address   peer-group-name} send-community	Specify that the COMMUNITIES attribute be sent to the fneighbor at this IP address.
neighbor {ip-address   peer-group-name} update-source interface	Allow internal BGP sessions to use any operational interface for TCP connections.
neighbor {ip-address   peer-group-name} ebgp-multihop	Allow BGP sessions, even when the neighbor is not on a directly connected segment. The multihop session is not established if the only route to the multi-hop peer's address is the default route (0.0.0.0).

Command	Purpose
neighbor {ip-address   peer-group-name} advertisement-interval seconds	Set the minimum interval between sending BGP routing updates.
neighbor {ip-address   peer-group-name} maximum-prefix maximum [threshold] [warning-only]	Limit the number of prefixes allowed from a neighbor.
neighbor {ip-address   peer-group-name} password string	Invoke MD5 authentication on a TCP connection to a BGP peer.
neighbor {ip-address   peer-group-name} weight weight	Specify a weight for all routes from a neighbor.
neighbor {ip-address   peer-group-name} distribute-list {access-list-number   name} {in   out}	Filter BGP routing updates to/from neighbors, as specified in an access list.
neighbor {ip-address   peer-group-name} filter-list access-list-number {in   out   weight weight}	Establish a BGP filter.
neighbor {ip-address   peer-group-name} next-hop-self	Disable next-hop processing on the BGP updates to a neighbor.
neighbor {ip-address   peer-group-name} version value	Specify the BGP version to use when communicating with a neighbor.
neighbor {ip-address   peer-group-name} route-map map-name {in   out}	Apply a route map to incoming or outgoing routes.
neighbor {ip-address   peer-group-name} soft-reconfiguration inbound	Configure the software to start storing received updates.
	This command requires at least one keyword. Currently the only keyword available is inbound, so the use of inbound is not optional.

If a peer group is not configured with a remote-as, the members can be configured with the **neighbor** remote-as command. This allows you to create peer groups containing EBGP neighbors.

You can customize inbound policies for peer group members, (using, for example, a distribute list, route map, or filter list) because one identical copy of an update is sent to every member of a group. Therefore, neighbor options related to outgoing updates cannot be customized for peer group members.

External BGP peers normally must reside on a directly connected network. Sometimes it is useful to relax this restriction in order to test BGP; do so by specifying the **neighbor ebgp-multihop** command.

Note To avoid the accidental creation of loops through oscillating routes, the multihop session will not be established if the only route to the multihop peer's address is the default route (0.0.0.0).

Members of a peer group can pass routes from one member of the peer group to another. For example, if router B is peering with routers A and C, router B can pass router A's routes to router C. For internal BGP, you might want to allow your BGP connections to stay up regardless of which interface is used to reach a neighbor. To do this, you first configure a *loopback* interface and assign it an IP address. Next, configure the BGP update source to be the loopback interface. Finally, configure your neighbor to use the address on the loopback interface. Now the IBGP session will be up as long as there is a route, regardless of any interface.

You can set the minimum interval of time between BGP routing updates.

You can invoke MD5 authentication between two BGP peers, meaning that each segment sent on the TCP connection between them is verified. This feature must be configured with the same password on both BGP peers; otherwise, the connection between them will not be made. The authentication feature uses the MD5 algorithm. Invoking authentication causes the Cisco IOS software to generate and check the MD5 digest of every segment sent on the TCP connection. If authentication is invoked and a segment fails authentication, then a message appears on the console.

See the "TCP MD5 Authentication for BGP Example" at the end of this chapter for an example of enabling MD5 authentication.

#### Make Neighbors Members of the Peer Group

Finally, to configure a BGP neighbor to be a member of that BGP peer group, use the following command in router configuration mode, using the same peer group name:

Command	Purpose
neighbor ip-address peer-group peer-group-name	Make a BGP neighbor a member of the peer group.

See the "BGP Peer Group Examples" section at the end of this chapter for examples of IBGP and EBGP peer groups.

### Disabling a Peer or Peer Group

To disable an existing BGP neighbor or neighbor peer group, use the following command in router configuration mode:

Command	Purpose
neighbor {ip-address   peer-group-name} shutdown	Shutdown or disable a BGP neighbor or peer
	group.

To enable a previously existing neighbor or neighbor peer group that had been disabled using the **neighbor shutdown** command, use the following command in router configuration mode:

Command	Purpose
no neighbor {ip-address   peer-group-name} shutdown	Enable a BGP neighbor or peer group.

### Indicate Backdoor Routes

You can indicate which networks are reachable by using a *backdoor* route that the border router should use. A backdoor network is treated as a local network, except that it is not advertised. To configure backdoor routes, use the following command in router configuration mode:

Command	Purpose
network address backdoor	Indicate reachable networks through backdoor routes.

# Modify Parameters While Updating the IP Routing Table

By default, when a BGP route is put into the IP routing table, the MED is converted to an IP route metric, the BGP next hop is used as the next hop for the IP route, and the tag is not set. However, you can use a route map to perform mapping. To modify metric and tag information when the IP routing table is updated with BGP learned routes, use the following command in router configuration

Command	Purpose
table-map route-map name	Apply a route map to routes when updating the IP routing table.

### Set Administrative Distance

Administrative distance is a measure of the preference of different routing protocols. BGP uses three different administrative distances: external, internal, and local. Routes learned through external BGP are given the external distance, routes learned with internal BGP are given the internal distance, and routes that are part of this autonomous system are given the local distance. To assign a BGP administrative distance, use the following command in router configuration mode:

Command	Purpose
<b>distance bgp</b> external-distance internal-distance local-distance	Assign a BGP administrative distance.

Changing the administrative distance of BGP routes is considered dangerous and generally is not recommended. The external distance should be lower than any other dynamic routing protocol, and the internal and local distances should be higher than any other dynamic routing protocol.

### **Adjust BGP Timers**

BGP uses certain timers to control periodic activities such as the sending of keepalive messages, and the interval after not receiving a keepalive message after which the Cisco IOS software declares a peer dead. By default, the keepalive timer is 60 seconds, and the holdtime timer is 180 seconds. You can adjust these timers. When a connection is started, BGP will negotiate the hold time with the neighbor. The smaller of the two hold times will be chosen. The keepalive timer is then set based on the negotiated hold time and the configured keepalive time. To adjust BGP timers for all neighbors, use the following command in router configuration mode:

Command	Purpose
timers bgp keepalive holdtime	Adjust BGP timers for all neighbors.

To adjust BTP keepalive and holdtime timers for a specific neighbor, use the following command in router configuration mode:

Command	Purpose
<b>neighbor</b> [ip-address   peer group-name] <b>timers</b> keepalive holdtime	Sets the keepalive and holdtime timers (in seconds) for the specified peer or peer group.

**Note** The timers configured for a specific neighbor or peer group override the timers configured for all BGP neighbors using the timers bgp command.

To clear the timers for a BGP neighbor or peer group, use the **no** form of the **neighbor timers** command.

### Change the Local Preference Value

You can define a particular path as more preferable or less preferable than other paths by changing the default local preference value of 100. To assign a different default local preference value, use the following command in router configuration mode:

Command	Purpose
bgp default local-preference value	Change the default local preference value.

You can use route maps to change the default local preference of specific paths. See the "BGP Route Map Examples" section at the end of this chapter for examples when used with BGP route maps.

### Redistribute Network 0.0.0.0

By default, you are not allowed to redistribute network 0.0.0.0. To permit the redistribution of network 0.0.0.0, use the following command in router configuration mode:

Command	Purpose
default-information originate	Allow the redistribution of network 0.0.0.0 into BGP.

# Configure the Router to Consider a Missing MED as Worst Path

To configure the router to consider a path with a missing MED attribute as the worst path, use the following command in router configuration mode:

Command	Purpose
bgp bestpath missing-as-worst	Configures the router to consider a missing MED as having a value of infinity, making the path without a MED value the least desirable path.

### Select Path Based on MEDs from Other Autonomous Systems

The MED is one of the parameters that is considered when selecting the best path among many alternative paths. The path with a lower MED is preferred over a path with a higher MED.

By default, during the best-path selection process, MED comparison is done only among paths from the same autonomous system. You can allow comparison of MEDs among paths regardless of the autonomous system from which the paths are received. To do so, use the following command in router configuration mode:

Command	Purpose
bgp always-compare-med	Allow the comparison of MEDs for paths from neighbors in different autonomous systems.

# Configure the Router to Use the MED to Choose a Path from Sub-AS Paths

To configure the router to consider the MED value in choosing a path, use the following command in router configuration mode:

Command	Purpose
bgp bestpath med-confed	Configures the router to consider the MED in choosing a path from among those advertised by different sub-ASs within a confederation.

The comparison between MEDs is only made if there are no external ASes in the path (an external AS is an AS that is not within the confederation). If there is an external AS in the path, then the external MED is passed transparently through the confederation, and the comparison is not made.

For e and we are comparing route A with these paths:

```
path= 65000 65004, med=2
path= 65001 65004, med=3
path= 65002 65004, med=4
path= 65003 1, med=1
```

In this case, path 1 would be chosen if **bgp bestpath med-confed** is enabled. The fourth path has a lower MED, but it is not involved in the MED comparison because there is an external AS in this path.

### Configure the Router to Use the MED to Choose a Path in a Confederation

To configure the router to use the MED to select the best path from among paths advertised by a single sub-AS within a confederation, use the following command in router configuration mode:

Command	Purpose
bgp deterministic med	Configures the router to consider the MED in choosing the best path from among paths advertised by a single sub-AS within the confederation.

Note If bgp always-compare-med is enabled, all paths are fully comparable, including those from other ASes in the confederation, even if **bgp deterministic med** is also enabled.

### Configure Route Dampening

Route dampening is a BGP feature designed to minimize the propagation of flapping routes across an internetwork. A route is considered to be flapping when it is repeatedly available, then unavailable, then available, then unavailable, and so on.

For example, consider a network with three BGP autonomous systems: AS 1, AS 2, and AS 3. Suppose the route to network A in AS 1 flaps (it becomes unavailable). Under circumstances without route dampening, AS 1's EBGP neighbor to AS 2 sends a Withdraw message to AS 2. The border router in AS 2, in turn, propagates the Withdraw to AS 3. When the route to network A reappears, AS 1 sends an Advertisement to AS 2, which sends it to AS 3. If the route to network A repeatedly becomes unavailable, then available, many Withdrawals and Advertisements are sent. This is a problem in an internetwork connected to the Internet because a route flap in the Internet backbone usually involves many routes.

Note No penalty is applied to a BGP peer reset when route dampening is enabled. Although the reset withdraws the route, there is no penalty applied in this instance, even if route flap dampening is enabled.

#### Minimize Flapping

The route dampening feature minimizes the flapping problem as follows. Suppose again that the route to network A flaps. The router in AS 2 (where route dampening is enabled) assigns network A a penalty of 1000 and moves it to "history" state. The router in AS 2 continues to advertise the status of the route to neighbors. The penalties are cumulative. When the route flaps so often that the penalty exceeds a configurable suppress limit, the router stops advertising the route to network A, regardless of how many times it flaps. Thus, the route is dampened.

The penalty placed on network A is decayed until the reuse limit is reached, upon which the route is once again advertised. At half of the reuse limit, the dampening information for the route to network A is removed.

### **Understand Route Dampening Terms**

The following terms are used when describing route dampening:

- Flap—A route is available, then unavailable, or vice versa.
- History state—After a route flaps once, it is assigned a penalty and put into "history state," meaning the router does not have the best path, based on historical information.
- Penalty—Each time a route flaps, the router configured for route dampening in another AS assigns the route a penalty of 1000. Penalties are cumulative. The penalty for the route is stored in the BGP routing table until the penalty exceeds the suppress limit. At that point, the route state changes from "history" to "damp."
- Damp state—In this state, the route has flapped so often that the router will not advertise this route to BGP neighbors.
- Suppress limit—A route is suppressed when its penalty exceeds this limit. The default value is
- Half-life—Once the route has been assigned a penalty, the penalty is decreased by half after the half-life period (which is 15 minutes by default). The process of reducing the penalty happens every 5 seconds.
- Reuse limit—As the penalty for a flapping route decreases and falls below this reuse limit, the route is unsuppressed. That is, the route is added back to the BGP table and once again used for forwarding. The default reuse limit is 750. The process of unsuppressing routes occurs at 10-second increments. Every 10 seconds, the router finds out which routes are now unsuppressed and advertises them to the world.
- Maximum suppress limit—This value is the maximum amount of time a route can be suppressed. The default value is 4 times the half-life.

The routes external to an AS learned via IBGP are not dampened. This policy prevent the IBGP peers from having a higher penalty for routes external to the AS.

#### **Enable Route Dampening**

To enable BGP route dampening, use the following command in global configuration mode:

Command	Purpose
bgp dampening	Enable BGP route dampening.

To change the default values of various dampening factors, use the following command in global configuration mode:

Command	Purpose
<b>bgp dampening</b> half-life reuse suppress max-suppress [route-map map]	Change the default values of route dampening factors.

### Monitor and Maintain BGP Route Dampening

You can monitor the flaps of all the paths that are flapping. The statistics will be deleted once the route is not suppressed and is stable for at least one half-life. To display flap statistics, use the following commands in EXEC mode:

Command	Purpose
show ip bgp flap-statistics	Display BGP flap statistics for all paths.
show ip bgp flap-statistics regexp regexp	Display BGP flap statistics for all paths that match the regular expression.
show ip bgp flap-statistics filter-list list	Display BGP flap statistics for all paths that pass the filter.
show ip bgp flap-statistics address mask	Display BGP flap statistics for a single entry.
show ip bgp flap-statistics address mask longer-prefix	Display BGP flap statistics for more specific entries.

To clear BGP flap statistics (thus making it less likely that the route will be dampened), use the following commands in EXEC mode:

Command	Purpose
clear ip bgp flap-statistics	Clear BGP flap statistics for all routes.
clear ip bgp flap-statistics regexp regexp	Clear BGP flap statistics for all paths that match the regular expression.
clear ip bgp flap-statistics filter-list list	Clear BGP flap statistics for all paths that pass the filter.
clear ip bgp flap-statistics address mask	Clear BGP flap statistics for a single entry.
clear ip bgp address flap-statistics	Clear BGP flap statistics for all paths from a neighbor.

Note The flap statistics for a route are also cleared when a BGP peer is reset. Although the reset withdraws the route, there is no penalty applied in this instance, even if route flap dampening is enabled.

Once a route is dampened, you can display BGP route dampening information, including the time remaining before the dampened routes will be unsuppressed. To display the information, use the following command in EXEC mode:

Command	Purpose
show ip bgp dampened-paths	Display the dampened routes, including the time remaining before they will be unsuppressed.

You can clear BGP route dampening information and unsuppress any suppressed routes by using the following command in EXEC mode:

Command	Purpose
clear ip bgp dampening [address mask]	Clear route dampening information and
	unsuppress the suppressed routes.

### **Monitor and Maintain BGP**

You can remove all contents of a particular cache, table, or database. You also can display specific statistics. The following sections describe each of these tasks.

### Clear Caches, Tables, and Databases

You can remove all contents of a particular cache, table, or database. Clearing a cache, table, or database can become necessary when the contents of the particular structure have become, or are suspected to be, invalid.

The following table lists the tasks associated with clearing caches, tables, and databases for BGP. Use these commands in EXEC mode:

Command	Purpose
clear ip bgp address	Reset a particular BGP connection.
clear ip bgp *	Reset all BGP connections.
clear ip bgp peer-group tag	Remove all members of a BGP peer group.

### Display System and Network Statistics

You can display specific statistics such as the contents of BGP routing tables, caches, and databases. Information provided can be used to determine resource utilization and solve network problems. You can also display information about node reachability and discover the routing path your device's packets are taking through the network.

To display various routing statistics, use the following commands in EXEC mode:

Command	Purpose
show ip bgp prefix	Display peer groups and peers not in peer groups to which the prefix has been advertised.
show ip bgp cidr-only	Display all BGP routes that contain subnet and supernet network masks.
show ip bgp community community-number [exact]	Display routes that belong to the specified communities.
show ip bgp community-list community-list-number [exact]	Display routes that are permitted by the community list.
show ip bgp filter-list access-list-number	Display routes that are matched by the specified autonomous system path access list.
show ip bgp inconsistent-as	Display the routes with inconsistent originating autonomous systems.
show ip bgp regexp regular-expression	Display the routes that match the specified regular expression entered on the command line.
show ip bgp [network] [network-mask] [subnets]	Display the contents of the BGP routing table.
show ip bgp neighbors [address]	Display detailed information on the TCP and BGP connections to individual neighbors.
show ip bgp neighbors [address] [received-routes   routes   advertised-routes   paths regular-expression   dampened-routes]	Display routes learned from a particular BGP neighbor.

Command	Purpose
show ip bgp paths	Display all BGP paths in the database.
show ip bgp peer-group [tag] [summary]	Display information about BGP peer groups.
show ip bgp summary	Display the status of all BGP connections.

### Log Changes in Neighbor Status

To enable the logging of messages generated when a BGP neighbor resets, comes up, or goes down, use the following command in router configuration mode:

Command	Purpose
bgp log-neighbor-changes	Log messages generated when a BGP neighbor goes up or down, or resets

- BGP Community with Route Maps Examples

### **BGP Route Map Examples**

The following example shows how you can use route maps to modify incoming data from a neighbor. Any route received from 140.222.1.1 that matches the filter parameters set in autonomous system access list 200 will have its weight set to 200 and its local preference set to 250, and it will be accepted.

```
router bgp 100
!
  neighbor 140.222.1.1 route-map fix-weight in
  neighbor 140.222.1.1 remote-as 1
!
route-map fix-weight permit 10
  match as-path 200
  set local-preference 250
  set weight 200
!
ip as-path access-list 200 permit ^690$
ip as-path access-list 200 permit ^1800
```

In the following example, route map freddy marks all paths originating from autonomous system 690 with a Multi Exit Discriminator (MED) metric attribute of 127. The second permit clause is required so that routes not matching autonomous system path list 1 will still be sent to neighbor 1.1.1.1.

```
router bgp 100
neighbor 1.1.1.1 route-map freddy out
!
ip as-path access-list 1 permit ^690_
ip as-path access-list 2 permit .*
route-map freddy permit 10
match as-path 1
set metric 127
route-map freddy permit 20
match as-path 2
```

The following example shows how you can use route maps to modify incoming data from the IP forwarding table:

```
router bgp 100
redistribute igrp 109 route-map igrp2bgp
route-map igrp2bgp
match ip address 1
set local-preference 25
set metric 127
set weight 30000
set next-hop 192.92.68.24
set origin igp
access-list 1 permit 131.108.0.0 0.0.255.255
access-list 1 permit 160.89.0.0 0.0.255.255
access-list 1 permit 198.112.0.0 0.0.127.255
```

It is proper behavior to not accept any autonomous system path not matching the **match** clause of the route map. This means that you will not set the metric and the Cisco IOS software will not accept the route. However, you can configure the software to accept autonomous system paths not matched in the match clause of the route map command by using multiple maps of the same name, some without accompanying set commands.

```
route-map fnord permit 10
match as-path 1
set local-preference 5
route-map fnord permit 20
match as-path 2
```

The following example shows how you can use route maps in a reverse operation to set the route tag (as defined by the BGP/OSPF interaction document, RFC 1403) when exporting routes from BGP into the main IP routing table:

```
router bgp 100
table-map set_ospf_tag
route-map set_ospf_tag
match as-path 1
set automatic-tag
1
ip as-path access-list 1 permit .*
```

In the following example, the route map called *set-as-path* is applied to outbound updates to the neighbor 200.69.232.70. The route map will prepend the autonomous system path "100 100" to routes that pass access list 1. The second part of the route map is to permit the advertisement of other routes.

```
router bgp 100
network 171.60.0.0
network 172.60.0.0
neighbor 200.69.232.70 remote-as 200
neighbor 200.69.232.70 route-map set-as-path out!
route-map set-as-path 10 permit
match address 1
set as-path prepend 100 100
!
route-map set-as-path 20 permit
match address 2
!
access-list 1 permit 171.60.0.0 0.0.255.255
access-list 1 permit 172.60.0.0 0.0.255.255
!
access-list 2 permit 0.0.0.0 255.255.255
```

Inbound route-maps could do prefix-based matching and set various parameters of the update. Inbound prefix matching is available in addition to as-path and community-list matching. In the following example, the **set local preference** command sets the local preference of the inbound prefix 140.10.0.0/16 to 120.

```
!
router bgp 100
network 131.108.0.0
neighbor 131.108.1.1 remote-as 200
neighbor 131.108.1.1 route-map set-local-pref in !
route-map set-local-pref permit 10
match ip address 2
set local preference 120
!
route-map set-local-pref permit 20
!
access-list 2 permit 140.10.0.0 0.0.255.255 access-list 2 deny any
```

The following examples show how to ensure that traffic from one router on a shared LAN will always be passed through a second router, rather than being sent directly to a third router on the same LAN.

Routers A, B, and C connect to the same LAN. Router A peers with B, and B peers with C. B sends traffic over the routes of router A to router C, but wants to make sure that all traffic from C to A goes through B, rather than directly from C to A over the shared LAN. This configuration can be useful for traffic accounting purposes or to satisfy the peering agreement between C and B. You can achieve this configuration by using the **set ip next-hop** command as shown in the following two examples.

Example 1 applies an inbound route map on the BGP session of router C with router B.

#### Router A:

```
router bgp 100
neighbor 1.1.1.2 remote-as 200
Router B:
```

```
router bgp 200
neighbor 1.1.1.1 remote-as 100
neighbor 1.1.1.3 remote-as 300
```

#### Router C:

```
router bgp 300
 neighbor 1.1.1.2 remote-as 200
neighbor 1.1.1.2 route-map set-peer-address in
route-map set-peer-address permit 10
 set ip next-hop peer-address
```

Example 2 applies an outbound route map on the BGP session of router B with router C.

#### Router A:

```
router bgp 100
   neighbor 1.1.1.2 remote-as 200
Router B:
  router bap 200
   neighbor 1.1.1.1 remote-as 100
   neighbor 1.1.1.3 remote-as 300
   neighbor 1.1.1.3 route-map set-peer-address out
  route-map set-peer-address permit 10
   set ip next-hop peer-address
Router C:
  router bgp 300
```

# **BGP Neighbor Configuration Examples**

In the following example, a BGP router is assigned to autonomous system 109, and two networks are listed as originating in the autonomous system. Then the addresses of three remote routers (and their autonomous systems) are listed. The router being configured will share information about networks 131.108.0.0 and 192.31.7.0 with the neighbor routers. The first router listed is in a different autonomous system; the second **neighbor** command specifies an internal neighbor (with the same autonomous system number) at address 131.108.234.2; and the third neighbor command specifies a neighbor on a different autonomous system.

```
router bgp 109
network 131.108.0.0
network 192.31.7.0
neighbor 131.108.200.1 remote-as 167
neighbor 131.108.234.2 remote-as 109
neighbor 150.136.64.19 remote-as 99
```

neighbor 1.1.1.2 remote-as 200

In Figure 33, Router A is being configured. The internal BGP neighbor is not directly linked to Router A. External neighbors (in autonomous system 167 and autonomous system 99) must be linked directly to Router A.

### Configure Route Filtering Using a Prefix List

The following example denies the default route 0.0.0.0/0:

```
ip prefix-list abc deny 0.0.0.0/0
```

The following example permits a route that matches the prefix 35.0.0.0/8:

```
ip prefix-list abc permit 35.0.0.0/8
```

In the following example, the BGP process only accepts prefixes with a prefix length of /8 to /24:

```
router bgp
version 2
network 101.20.20.0
distribute-list prefix max24 in
!
ip prefix-list max24 seq 5 permit 0.0.0.0/0 ge 8 le 24 !
```

The following configuration can be used to conditionally originate a default route (0.0.0.0/0) in RIP when there exists a prefix 10.1.1.0/24 in the routing table:

```
ip prefix-list cond permit 10.1.1.0/24
!
route-map default-condition permit 10
match ip address prefix-list cond
!
router rip
default-information originate route-map default-condition !
```

In the following configuration, BGP accepts routing updates from 193.1.1.1 only, besides filtering on the prefix length:

```
router bgp
distribute-list prefix max24 gateway allowlist in !
ip prefix-list allowlist seq 5 permit 192.1.1.1/32 !
```

In the following example, BGP filters incoming updates to the prefix using *name1*, and matches the gateway (next-hop) of the prefix being updated to the prefix list *name2*, on the interface ethernet 0.

```
router bgp 103 distribute-list prefix name1 gateway name2 in ethernet 0.
```

#### Configure Route Filtering by Specifying a Group of Prefixes

The following example permits routes with prefix length up to 24 in network 192/8:

```
ip prefix-list abc permit 192.0.0.0/8 le 24
```

The following example denies routes with prefix length greater than in 25 in 192/8:

```
ip prefix-list abc deny 192.0.0.0/8 ge 25
```

The following example permits routes with prefix length greater than 8 and less than 24 in all address space:

```
ip prefix-list abc permit 0.0.0.0/0 ge 8 le 24
```

The following example denies routes with prefix length greater than 25 in all address space:

```
ip prefix-list abc deny 0.0.0.0/0 ge 25
```

This example denies all routes in 10/8, since any route in the Class A network 10.0.0.0/8 is denied if its mask is less than or equal to 32 bits:

```
ip prefix-list abc deny 10.0.0.0/8 le 32
```

The following example denies routes with a mask greater than 25 in 204.70.1/24:

```
ip prefix-list abc deny 204.70.1.0/24 ge 25
```

The following example permits all routes:

```
ip prefix-list abc permit 0.0.0.0/0 le 32
```

#### Adding or Deleting Prefix List Entries

You can add or delete individual entries in a prefix list. For example, if a prefix list has the following initial configuration:

```
ip prefix-list abc deny 0.0.0.0/0 le 7
ip prefix-list abc deny 0.0.0.0/0 ge 25
ip prefix-list abc permit 35.0.0.0/8
ip prefix-list abc permit 204.70.0.0/15
```

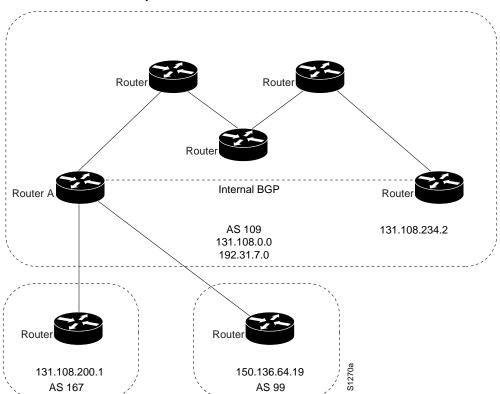

The following configuration changes the prefix list so that 204.70.0.0 is not permitted and a new entry permits 198.0.0.0/8:

```
no ip prefix-list abc permit 204.70.0.0/15 ip prefix-list abc permit 198.0.0.0/8
```

#### The new configuration is:

```
ip prefix-list abc deny 0.0.0.0/0 le 7
ip prefix-list abc deny 0.0.0.0/0 ge 25
ip prefix-list abc permit 35.0.0.0/8
ip prefix-list abc permit 198.0.0.0/8
```

Figure 33 Assigning Internal and External BGP NeighborsBGP Synchronization Example

In the configuration shown in Figure 34, with synchronization on, Router B does not advertise network 198.92.68.0 to Router A until an IGRP route for network 198.92.68.0 exists. If you specify the **no synchronization** router configuration command, Router B advertises network 198.92.68.0 as soon as possible. However, because routing information still must be sent to interior peers, you must configure a full internal BGP mesh.

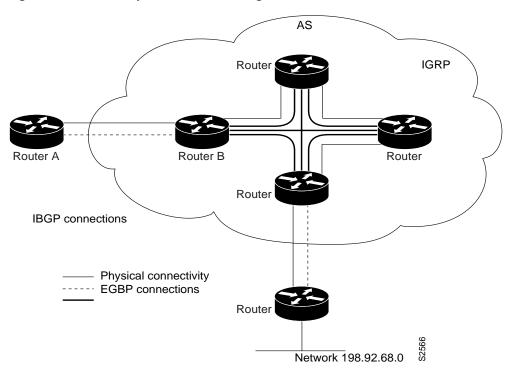

Figure 34 BGP Synchronization Configuration

## BGP Path Filtering by Neighbor Example

The following is an example of BGP path filtering by neighbor. The routes that pass as-path access list 1 will get weight 100. Only the routes that pass as-path access list 2 will be sent to 193.1.12.10. Similarly, only routes passing access list 3 will be accepted from 193.1.12.10.

```
router bgp 200
neighbor 193.1.12.10 remote-as 100
neighbor 193.1.12.10 filter-list 1 weight 100
neighbor 193.1.12.10 filter-list 2 out
neighbor 193.1.12.10 filter-list 3 in
ip as-path access-list 1 permit _109_
ip as-path access-list 2 permit _200$
ip as-path access-list 2 permit ^100$
ip as-path access-list 3 deny _690$
ip as-path access-list 3 permit .*
```

## **BGP Aggregate Route Examples**

The following examples show how you can use aggregate routes in BGP either by redistributing an aggregate route into BGP or by using the conditional aggregate routing feature.

In the following example, the **redistribute static** command is used to redistribute aggregate route 193.\*.\*.\*:

```
ip route 193.0.0.0 255.0.0.0 null 0
!
router bgp 100
 redistribute static
```

The following configuration creates an aggregate entry in the BGP routing table when there is at least one specific route that falls into the specified range. The aggregate route will be advertised as coming from your autonomous system and has the atomic aggregate attribute set to show that information might be missing. (By default, atomic aggregate is set unless you use the as-set keyword in the aggregate-address command.)

```
router bgp 100
 aggregate-address 193.0.0.0 255.0.0.0
```

The following example creates an aggregate entry using the same rules as in the previous example, but the path advertised for this route will be an AS\_SET consisting of all elements contained in all paths that are being summarized:

```
router bgp 100
 aggregate-address 193.0.0.0 255.0.0.0 as-set
```

The following example not only creates the aggregate route for 193.\*.\*.\*, but will also suppress advertisements of more specific routes to all neighbors:

```
router bgp 100
 aggregate-address 193.0.0.0 255.0.0.0 summary-only
```

### **BGP Conditional Advertisement Configuration Examples**

This section provides a configuration example of the BGP Conditional Advertisement feature. In the following example, the *ip-address* argument refers to the IP address of the neighbor, and the map1-name arguments and map2-name, refer to the names of the route maps:

```
neighbor{ip-address} advertise-map {map1-name} non-exist-map {map2-name}
no neighbor{ip-address} advertise-map {map1-name} non-exist-map {map2-name}
```

The route map associated with the non-exist-map specifies the prefix that the BGP speaker tracks. The route map associated with the advertise map specifies the prefix that is advertised when the prefix in the non-exist-map no longer exists. The prefix tracked by the BGP speaker must be present in the IP routing table for the conditional advertisement not to take place. In the following example, the router advertises 172.16.0.0/16 to its neighbor only if 192.168.7.0/24 is not present in the IP routing table.

To conditionally advertise a set of routes, use the following commands in router configuration mode:

```
router bap 109
neighbor 10.89.2.33 remote-as 2051
neighbor 10.89.2.33 advertise-map map1-name non-exist-map map2-name
route-map map1-name permit 10
match ip address 1
route-map map2-name permit 10
match ip address 2
access-list 1 permit 172.16.0.0
access-list 2 permit 192.168.7.0
```

### **BGP Confederation Example**

The following is a sample configuration from several peers in a confederation. The confederation consists of three internal autonomous systems with autonomous system numbers 6001, 6002, and 6003. To the BGP speakers outside the confederation, the confederation looks like a normal autonomous system with autonomous system number 666 (specified via the **bgp confederation identifier** command).

In a BGP speaker in autonomous system 6001, the **bgp confederation peers** command marks the peers from autonomous systems 6002 and 6003 as special EBGP peers. Hence peers 171.69.232.55 and 171.69.232.56 will get the local-preference, next-hop and MED unmodified in the updates. The router at 160.69.69.1 is a normal EBGP speaker and the updates received by it from this peer will be just like a normal EBGP update from a peer in autonomous system 666.

```
router bgp 6001
bgp confederation identifier 666
bgp confederation peers 6002 6003
neighbor 171.69.232.55 remote-as 6002
neighbor 171.69.232.56 remote-as 6003
neighbor 160.69.69.1 remote-as 777
```

In a BGP speaker in autonomous system 6002, the peers from autonomous systems 6001 and 6003 are configured as special EBGP peers. 170.70.70.1 is a normal IBGP peer and 199.99.99.2 is a normal EBGP peer from autonomous system 700.

```
router bgp 6002
bgp confederation identifier 666
bgp confederation peers 6001 6003
neighbor 170.70.70.1 remote-as 6002
neighbor 171.69.232.57 remote-as 6001
neighbor 171.69.232.56 remote-as 6003
neighbor 199.99.99.2 remote-as 700
```

In a BGP speaker in autonomous system 6003, the peers from autonomous systems 6001 and 6002 are configured as special EBGP peers. 200.200.200.200.200 is a normal EBGP peer from autonomous system 701.

```
router bgp 6003
bgp confederation identifier 666
bgp confederation peers 6001 6002
neighbor 171.69.232.57 remote-as 6001
neighbor 171.69.232.55 remote-as 6002
neighbor 200.200.200.200 remote-as 701
```

The following is a part of the configuration from the BGP speaker 200.200.200.205 from autonomous system 701. Neighbor 171.69.232.56 is configured as a normal EBGP speaker from autonomous system 666. The internal division of the autonomous system into multiple autonomous systems is not known to the peers external to the confederation.

```
router bgp 701
neighbor 171.69.232.56 remote-as 666
neighbor 200.200.200.205 remote-as 701
```

# TCP MD5 Authentication for BGP Example

The following example specifies that the router and its BGP peer at 145.2.2.2 invoke MD5 authentication on the TCP connection between them:

```
router bgp 109 neighbor 145.2.2.2 password v6lne0qkel33&
```

### BGP Peer Group Examples

This section contains an IBGP peer group example and an EBGP peer group example.

#### **IBGP Peer Group Example**

In the following example, the peer group named *internal* configures the members of the peer group to be IBGP neighbors. By definition, this is an IBGP peer group because the router bgp command and the **neighbor remote-as** command indicate the same autonomous system (in this case, AS 100). All the peer group members use loopback 0 as the update source and use set-med as the outbound route-map. The example also shows that, except for the neighbor at address 171.69.232.55, all the neighbors have filter-list 2 as the inbound filter list.

```
router bap 100
neighbor internal peer-group
neighbor internal remote-as 100
neighbor internal update-source loopback 0
neighbor internal route-map set-med out
neighbor internal filter-list 1 out
neighbor internal filter-list 2 in
neighbor 171.69.232.53 peer-group internal
neighbor 171.69.232.54 peer-group internal
neighbor 171.69.232.55 peer-group internal
neighbor 171.69.232.55 filter-list 3 in
```

#### **EBGP Peer Group Example**

In the following example, the peer group external-peers is defined without the neighbor remote-as command. This is what makes it an EBGP peer group. Each member of the peer group is configured with its respective autonomous system number separately. Thus, the peer group consists of members from autonomous systems 200, 300, and 400. All the peer group members have set-metric route map as an outbound route map and filter-list 99 as an outbound filter list. Except for neighbor 171.69.232.110, all have 101 as the inbound filter list.

```
router bgp 100
neighbor external-peers peer-group
 neighbor external-peers route-map set-metric out
neighbor external-peers filter-list 99 out
neighbor external-peers filter-list 101 in
neighbor 171.69.232.90 remote-as 200
 neighbor 171.69.232.90 peer-group external-peers
 neighbor 171.69.232.100 remote-as 300
neighbor 171.69.232.100 peer-group external-peers
neighbor 171.69.232.110 remote-as 400
neighbor 171.69.232.110 peer-group external-peers
 neighbor 171.69.232.110 filter-list 400 in
```

### **BGP Community with Route Maps Examples**

This section contains three examples of the use of BGP communities with route maps.

In the first example, the route map *set-community* is applied to the outbound updates to the neighbor 171.69.232.50. The routes that pass access list 1 have the special community attribute value "no-export." The remaining routes are advertised normally. This special community value automatically prevents the advertisement of those routes by the BGP speakers in autonomous system 200.

```
router bgp 100
neighbor 171.69.232.50 remote-as 200
neighbor 171.69.232.50 send-community
neighbor 171.69.232.50 route-map set-community out
!
route-map set-community 10 permit
match address 1
set community no-export
!
route-map set-community 20 permit
match address 2
```

In the second example, the route map *set-community* is applied to the outbound updates to neighbor 171.69.232.90. All the routes that originate from AS 70 have the community values 200 200 added to their already existing values. All other routes are advertised as normal.

```
route-map bgp 200
neighbor 171.69.232.90 remote-as 100
neighbor 171.69.232.90 send-community
neighbor 171.69.232.90 route-map set-community out!
route-map set-community 10 permit
match as-path 1
set community 200 200 additive!
route-map set-community 20 permit
match as-path 2
!
ip as-path access-list 1 permit 70$
ip as-path access-list 2 permit .*
```

In the third example, community-based matching is used to selectively set MED and local-preference for routes from neighbor 171.69.232.55. All the routes that match community list 1 get the MED set to 8000. This includes any routes that have the communities "100 200 300" or "900 901." These routes could have other community values also.

All the routes that pass community list 2 get the local preference set to 500. This includes the routes that have community values 88 or 90. If they belong to any other community, they will not be matched by community list 2.

All the routes that match community list 3 get the local-preference set to 50. Community list 3 will match all the routes because all the routes are members of the Internet community. Thus, all the remaining routes from neighbor 171.69.232.55 get a local preference 50.

```
router bgp 200
neighbor 171.69.232.55 remote-as 100
neighbor 171.69.232.55 route-map filter-on-community in
route-map filter-on-community 10 permit
match community 1
set metric 8000
route-map filter-on-community 20 permit
match community 2 exact-match
set local-preference 500
route-map filter-on-community 30 permit
match community 3
set local-preference 50
ip community-list 1 permit 100 200 300
ip community-list 1 permit 900 901
ip community-list 2 permit 88
ip community-list 2 permit 90
1
ip community-list 3 permit internet
```

In the next example, the route map set-community is applied to the outbound updates to the neighbor 171.69.232.50. The routes that pass access list 1 have the special community attribute value "local-as." The remaining routes are advertised normally. This special community value automatically prevents the advertisement of those routes by the BGP speakers outside autonomous system 200.

```
router bgp 65000
network 1.0.0.0 route-map set-community
bgp confederation identifier 200
bgp confederation peers 65001
neighbor 171.69.232.50 remote-as 100
neighbor 171.69.233.2 remote-as 65001
route-map set-community permit 10
 set community local-as
```

In the following example, Confederation 100 contains three autonomous systems: 100, 200, and 300. For network 1.0.0.0, the route map set-local-as specifies that the advertised routes have the community attribute "local-as." These routes are not advertised to any EBGP peer outside the local autonomous system. For network 2.0.0.0, the route map set-no-export specifies that the routes advertised have the community attribute "no-export."

A route between router 6500 and router 65001 does not cross the boundary between autonomous systems within the confederation. A route between sub-autonomous systems for which router 65000 is the controlling router does not cross the boundary between the confederation and an external autonomous system, and also does not cross the boundary between sub-autonomous systems within the local autonomous system. A route to from router 65000 to router 65001 would not be acceptable for network 1.0.0.0 because it crosses the boundary between sub-autonomous systems within the confederation.

```
router bgp 65001
bgp confederation identifier 200
bgp confederation peer 65000
network 2.0.0.0 route-map set-community
neighbor 171.69.233.1 remote-as 65000
route-map set-community permit 10
set community no-export
```
